Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.digital.misc,rec.radio.amateur.homebrew

I would like to setup an link between 2 computers.
What's the maximum speed I can transmit on ?
Please give some solutions.

Thanks.

2. FS:AEA Antenna Analyst/Diamond SWR/PWR

For sale:

AEA SWR-121 HF antenna analyst. 1-31MHz. LCD shows graph of antenna
SWR points. FB condition. $350+ at AES. Will sell for $200 shipped.

Diamond SX-1000 SWR/PWR meter. 1.8MHz-1.3GHz, 5/20/200W ranges. A fine
looking meter in perfect condition. $250+ at AES. Will sell for $150 shipped.

Yep, but he was asking about *transceivers*, and neither the Drake
2NT nor those old Heath boat anchors were transceivers. The Century 21
is a transceiver.

I had overlooked the MFJ QRP CW single banders because they now have
QRP SSB single banders too (which I mistakenly assumed to be *instead*).
Oh, well. And there are all the little kit QRP rigs too. The majors
don't seem to be making CW only transceivers anymore, but there are
still some bit players in the game. Forgive me mighty MFJ. :-)

That doesn't erase the memory. It masks it. The info is still there, and by reversing the process you can reactivate it. It is just completely hidden in normal operation. For practical purposes this is _better_ than if it were erased, as it is easier to recover from a mistake. Also, it is in the manual, pg. 32, as I posted here a few days ago.

>a small rig that can work mobile also.
>It also fits my budget right now.

You might want to figure out how much it costs when you add all the
band units. $549 only buys you a monobander. You have to add $290 to
that to get all the HF bands, and you don't get a microphone, mounting
bracket, or the optional noise blanker, that's another $74.45. Sure, you
can add band units one at a time, *now*, but for how much longer? What'll
you do if they decide to quit making them next year and you don't have a
full set? And several people have commented on the disconcerting frequency
shifts as the microprocessor tries to compensate for PTO drift.

A full up Scout is going to cost you in the neighborhood of the
Alinco DX-70 (price recently reduced), and above what you'd pay
for a good used IC-735. Both of those are more radio for the money
than the Scout (IMHO anyway). Both of these alternatives run 100 watts,
compared to the Scout's 50 watts, both have general coverage receive,
which the Scout does not, and the DX-70 even has 6 meters. Both of
these radios include the microphone and mobile mounting bracket and
a noise blanker (essential for mobile operation). Both of these radios
have filter options and PBT or IF shift, VOX, memories, and the ability
to work split, etc.

Now the Scout seems to be Ok, and better than Ok in some respects,
but I think you should weigh other options (including the used
market) before jumping on this rig, especially if mobile operation
is a major consideration. (Think about where you'll store the band
units in the car.)

How about it people? This guy has had his interest sparked,
and he needs it from the very beginning. We don't know where
he is located, whether he has an active club in his area, or
a friend or family member in radio, we don't even know if there
is a Radio Shack or electronics place where he can buy books.
But he is on the internet. Does the ARRL have a web page where
he can order an introductory book?

>be badly misadjusted. It would seem however that the tube operates with
>low efficiency with the screen voltage reduced. This method does have
>the advantage that full power can be restored easily if needed.

This is a good method. The reason you're getting low output is because
you've reduced PA gain, exactly what you wanted.

>* Detune the "Antenna Coupling" L-C. Can this be done so the tube
>"idles" into a high impedance from the plate L-C circuit, but little
>power reaches the antenna?

You *don't* want to do this. Operating off resonance will cause the
tube to draw *lots* of current, and light loading will tend to make
the PA unstable.

>* Reduce the drive power (by detuning the grid circuit). This seems like
>a very bad idea, as the grid bias falls with less drive (about -40 V
>is supplied from the power supply, but it increases to -60 V or so with
>drive). That probably will make the tube draw excessive DC plate
>current.

Detuning the grid circuit will also tend to make the PA unstable.

Now you *could* bypass the PA stage entirely and just run off the
driver stage. Pull the PA tube and couple from the driver directly
to the output network (you'll likely need an L network where the
PA tube was). This may take some calculation and some cut and try,
but you'll not only save the final (it'll last a long time on
the shelf), but you'll get rid of the filament power draw too.

Omni VI owners:

The latest ROM is available from TEN-TEC for the Omni VI.
Check your current ROM version (get the complete version number, from
the "Logic" chip (28 pin DIP package) under the top cover of the radio).
Then call TEN-TEC's service department at (423) 428-0364 and they can
arrange to send you an updated version. Email me if you need a detailed
list of the new features available in the current ROM.

$15 for a trade-in of your current ROM (you pay return shipping)
$25 to purchase the new ROM outright

I just bought the new ROM, and once again, TEN-TEC is sending it out
and telling me "Just drop a check in the mail when you receive it."

What a great company.

15. Icom IC-T22A rcv. up to 480+Mhz

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-01 00:00:00 UTC
From: bpaul@qualcomm.com
Message-ID: <bpaul-0104961420210001@wpaul-mac.qualcomm.com>
Source record: 203526

After tuning around with my T22a, I realized I was hearing a 440 repaeter around 290 Mhz. After some experimentation with a signal generator I was able to come up with a pattern for this false imaging, and unfortunately it wasn't just an easy offset.
Anyway, I came up with an equaton that can be used to convert from actual frequency (AF) to the Icom frequency (IcomF) it can be received at:

((AF Mhz.) / 1.5) - 10.285 = (IcomF Mhz.)

So, 450Mhz. can be recieved at 289.720Mhz (actually 289.715, but the tuner will only step to 10KHz in that band.
The receive strength is pretty good (-110dBm @ 450Mhz vs. -122dBm @ 146Mhz.) and the main limitation becomes the antenna. I am using a Mag mount Larsen atnenna -single band tuned for 2m- and still picking up the local Sheriff on 450 with full signal strength. My rubber duckie antenna is enough to pick up 450, but it is alot less sensitive. I guess I should go out and by a dual or tri-band antenna now.

I also tested the tuner at all other frequencies, and the receiver is sensitive enough to be used from 54Mhz to 411Mhz by directly entering the frequency. The false image phenomena cuts out just above 480 Mhz.

What I can't figure out is how this night be happening inside the radio. It must be some kind of IF frequency - harmonics in the preamp type of thing, but I don't have a schematic for this thing.

Anyway, I thought other T22A owners might enjoy this extra coverage.

Don't forget the Heath HW-16. It was (is?...I still have one) meant for Novice use in the late 60's/early 70's. CW only on 80/40/15 meters (the Novice HF bands then). It was sort of an xcvr...crystal controlled xmtr (Novices were restricted to crystal control then) but tunable rcvr. You could add the HG-10 VFO. There were mods for making it a true xcvr and for changing the bands. Nice little rig for its time.

For more modern stuff, there are lots of nice CW only QRP (<5W output) rigs. Lots of good kits from the various QRP clubs. They're affordable (many <$100) and are really good performers. If you really gota have more power, there are some fairly simple amp circuits around for up to 50W.

There are a couple SSB QRP kits available too.

>73's Dick K8WHA

As a former owner of a Ten-Tec Century 21, I can vouch for it's wonderful QSK, but that's all I can vouch for. Other than QSK, the rig stunk. The receiver was lousy, the vfo had more backlash than a rubber band (yes, I'm exaggerating - but it was still bad), the filtering could have been much better, and the transmitter was underpowered for the size of the radio. Granted, I owned the very first iteration of the radio, and Ten-Tec did make vast improvements to the analog vfo, and eventually went with a digital option that became standard on the next gen. Century 22. But the rig had so much to be desired that I was left wishing for a 'real' all cw rig. Alas, Ten Tec abandoned the line after the '22. Too bad - an all cw rig with 100(+) watts out, DSP, a supersensitive receiver like the Omni VI, built-in memory keyer, and QSK would be a kick-butt kinda radio.....guess the niche is just too small.....dern shame.

Mike, WA2QIC

PS. I can also say that Ten-Tec Customer Service is truely unsurpassed in my book.....and I really, really miss Heathkit :(

24. WTB Remote antenna switch

I had the 735 and sold it after I purchased a new rig. The
rig I have now is an Icom IC-738 nice rig, but not a whole lot
of an upgrade from the 735. Stay away from the 728 it is an
intry level radio. I think it has more memories but you can
run over the 735 with a truck and it won't quit!

The 735 is going to go down in history! It was as poplar as the
IC706 is today. If I could aford it I would get another one
just as a spare for field day and other outings.

26. FS: 220 gear

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-01 00:00:00 UTC
From: "Yves Albert (Al \"Al\") Feder" <w1eox@ix.netcom.com>
Message-ID: <315FF55F.49A7@ix.netcom.com>
Source record: 203537

I'm getting off 220, and am selling these rigs to pay for some
144/440 gear we're putting in here.

HT's:

KENWOOD TH-315A, very little use. With case, small charger, manual.
$225.00 plus shipping.

TEMPO S-2, a veteran, but works great. Thumbwheel freq.selection,
factory installed tone board, telescoping and rubber ducky
antennas, manuals, case. $175.00 plus shipping.

MOBILE RIGS:

Icom 37A, with mike/manual. Used mobile. Works fine except at temps
below 10F (squeals, etc. - a lot of rigs die of fright until car warms
up!!!) $225.00 plus shipping.

Kenwood 321A, tone, mic, manual, etc. used mobile but in excellent
shape. $300.00 plus shipping.

NOTE: This rig goes with the companion 221A for "stacking" for two
meters as well. The 221A is also available TO THE BUYER OF THE 321A
(NOT SEPARATELY!) with the stacking mount, for an additional $200.00.

Kenwood 3530A, toneboard installed, mic, manual, etc. never used mobile.
A really nice 220 rig, more elaborate than the 321A but bigger, so I
used this one in the shack. $325.00 plus shipping.

Most (I think all actually) of the rigs come with factory boxes and
all paperwork.

e-mail replies only pleez.......
Thanks!

27. Re: Yaesu FT530 help!

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-01 00:00:00 UTC
From: kucharsk@netcom.com
Message-ID: <kucharskDp7JAC.5CE@netcom.com>
Source record: 203538

While reading article <315DD01E.2C7B@sprynet.com>, I noticed that
dblizzar@sprynet.com (Dave Blizzard) said the following:
>I recently bought a new FT530 from the local dealer but can't find a
>source for the coax plug used to power this HT from an external DC
>supply. As usual the manual doesn't provide the spec, all it says is
>either a 3.7mm or 4.0mm plug (depending on where you look in the
>manual) but the inside diameter is not specified. All the usual local
>sources don't have anything that will fit.

I don't know the size, but the Yaesu cord isn't exceptionally outrageously
priced at $6 or so - expensive for a cord, yes, but if it saves you a lot
of looking around or driving around town, it may be worth it...

29. Icom IC-T21A out of band receive ?

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-01 00:00:00 UTC
From: jmtallon@mtu.edu
Message-ID: <4jojdr$j2v@login.ee>
Source record: 203540

I did the mod used on the W21A to allow out of band recieve - hold down B & # while turning it on, then changes the places setting to 100... My question is this - how much of this out of band range can I actually pick up ? Did this mod just fool the cpu into thinking it can receive all the extra frequencies, or can the radio actually pick all the frequencies I can punch in ? Bueller ? Bueller ? BTW - I don't really have a out of band frequency to check - I just did the mod because I could :) Anyone have any advice/opinions/taunting ? Thanks in advance.

> BEST 73 ? ADI 4Z4VG

I have one and after you get it there is little need for other instruments for coax. I scoped out all my antennas with the 259 and am busy resetting them to optimum for where I work. Its all one unit...freq meter, very low power transmitter, resistance meter and is adaptable to grid dip per instructions.

The only thing to make sure is that the resistence is set (mine was about 5 ohms off at res.) The factory set the noise bridge, but not the 259. Only other problem : make sure you have no nearby commercial BC or shortwave station altho the unit is not as sensitive as the AEA analyst.

Well, for myself, HF *SSB* is the heart of HAM radio. For others it is
CW HF. For still others, it is 2M FM. Fighting over it is irrelavent. That is
like expecting all hams to agree on who makes the best radio (vhf,uhf,hf,etc).
I am an EXTRA class & worked hard for my ticket. However, the code
requirement WILL be dropped sooner or later. Operating as a third party just
ISN'T the same as operating when YOU want to. I well remember many a night,
very, very late & having a band open on HF with dozens of stations all of a
sudden calling me (SSB) !!!! Or very early, just before dawn catching New
Zealanders & Aussie's on 15M booming in ! (please don't throw rocks at me ,
I'm only 32 ! hi hi).
Ironically, I originally got my novice/tech ticket just to learn the
code to help me with my SWL'ing the ham bands. Now, I still practice the code
to keep from getting rusty, but I RARELY use CW!!! I am now looking to get
active on VHF/UHF SSB weak signal work! But HF SSB is still very important to
me. Anyway, now, no one will be a BETTER ham by knowing the code. Requiring
many more operating procedure questions on licensing exams WOULD likely make
more of a difference! Also, possibly requiring mock QSO's , if practical,
could be another useful idea. I.E. just because you know the code, DOESN'T
mean that you'll know how to act on the air!!!
However, for now, the code is the only way to HF, and HF SSB IS worth
the effort! Just my ($1.00 +) $0.02 worth. 73's

N4ZGT.

> I don't recall a CW only Drake, but the Ten-Tec Century 21 is a CW
> only rig I believe.

I had to think about this one too...I believe the Drake twins, 2NT (transmitter) and 2B or 2C receiver were set up as CW only. Maybe the 2NT also ran AM, but I dont recall.

Of course, the classics of yesteryear like Heath DX-40, DX-60 etc ran AM and CW...but most guys today use them as CW only rigs I would guess.

Others have mentioned the TenTec and Heath rigs. How about the MFJ qrp rigs, or the host of other mini QRP type rigs that are now on the market? I believe most are in the 5 to 10 watt range--dont know many over that power limit.

Afraid most other rigs of CW only variety are before my radio days.

>at the radio equipment site.
>Mat mat@clearnet.com

Mat,

Yes, I have... the important items are:

1. Get one designed to handle the power you intend to push thru it. Use a factor of 2X if possible. i.e. Transmitting 100 watts, get contacts that are rated to at least 200 watts.
2. Get a relay designed to match the frequency you intend to pass. i.e. You intend to switch 900 MHz, get one rated up to at least that frequency... the higher, the better. Sealed relays are best.
3. Watch the coil voltage. Often surplus coaxial relays will require 24 volts dc or 48 volts dc. I would strongly advise against any 120VAC coils even if you are willing to use a isolation transformens! Transformers can and DO short! Try to get a coil with low voltage that you can easily provide.
4. Plan on voltage drops because of long runs of coil voltage supply cable. Measure the voltage with the relay attached ~ at the antenna end. You want to be assured that the plunger completes a full stroke to assure proper switching!
5. Solder and weatherproof your exposed junctions and relays. Roofing tar works great! Get it in white, if you like.

>Gordon AB5DG
****
Gordon,

Condenser mikes require a small DC bias voltage to operate. Your crystal mike element does not. I suspect that voltage is still present. Also, I don't beleive the crystal element has the same impedance as the condenser element.

I suspect that you have some serious mis-match issues at work here.

First chech your manual and see if they offer any hints about using other types of mikes. Next, contact technical support at both ICOM and Heil; ask for the best plan of action... chances are, one or both have fought and won these same battles before!

I suspect that crystal mike will have PLENTY of drive once is 'sees' the correct input impedance at the radio!

Hi, Gene. I understand your reluctance to subject yourself to an "open ended" repair bill. I've had work done in Bellvue on several of my Icom radios, and most of it was done withing the one-hour charge (plus parts).

If your work is as simple as you say, there's nothing to worry about.

Perhaps someone else can recommend exactly what you're looking for, or a cheaper, independent service tech.

Hi,

I have an FT790R purchased in Europe and I am wondering if it possible to modify it to cover the extended US 70cm allocation (especially frequencies above 440MHz where I believe repeaters are located). Any information would be appreciated as the manual and schematics show that all sub models (A, B, C, D) only show frequency coverage from 430 to 440 MHz with varying repeater shifts and switch on frequencies.

Thanks
Nick F1VAT

>
> George, KG6GA
>
George: Drake did not make a cw only tranceiver. They produced the 2NT transmitter which was crystal controlled and matched up with their other receivers.

Heath produced the HW 16 novice cw tranceiver but requires an external vfo such as the HG 10 series. This rig runs on 80, 40 and 15 meters.

Heath produced the qrp series HW 7 and HW 8 and these rigs containthe vfos since they are common components for receive.

Ten Tec produced the Century 21 self contained cw only transceiver. Nice qsk!

Ten Tec also ran off about 800 Argonauts. This rig included sideband as well.

>5. Overall, how would you rate the rig?

Hi Dave: We have had an FT-8500 for almost 9 months now. Overall it is
a very well thought out rig. But if you are considering one, I have
the following:
1) We live in Calgary Alberta which is very susceptible to intermod &
this rig is no exception. I suppose it is OK but we do get periodic

bursts of it. Of course the downtown area is bad but without a fil
ter, I think any rig will give you intermod. I'm not terribly
bothered by what we do get.
2) We have used the autodialer & it works just fine.
4) I presume you are referring to the 'Mr Potatoe Head' mike: Overall
it is very good. It is lit for night-time use. However....watch the
volume controls....they don't lock at all & there is a definite
tendency for them to move & blow you out of the front seat!!! Also,
unlike the handhelds, you cannot mute the 'other band'. You either
have to mute UHF or VHF & that can be a real pain. We generally just
down the volume.
Other than that, I really like it. Quite a conversation piece!!
Good Luck!!!
2)

1.2 GHz Users

I am thinking of setting up a small 1.2 GHz repeater in the Milwaukee, WI area. I have heard a lot of rumors about the characteristics of this band that may make it difficult to use over a wide area in Milwaukee. I have not been able to talk to any one who has actually worked this frequency. I am wondering if the free path losses are so high that the range would be very limited? I also wonder if the penetration into buildings and cars would also be lower than on 2 meters?

I would appreciate your comments.

Jim

64. Synthesizer Tuning Noise

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-02 00:00:00 UTC
From: blanton@ni.net
Message-ID: <blanton-0204960722590001@xband.ni.net>
Source record: 203471
Cross-posted to: rec.radio.amateur.equipment,rec.radio.shortwave

On my Drake R-8A I�ve noticed a clicking or scratching noise that occurs when the synthesizer is tuned. This problem isn�t unique to the Drake receiver as I�ve also noticed it on Icom and Kenwood models. On the Drake it is very evident in certain frequency ranges (e.g., around 25 MHz and in some other bands) and is not observable at all in other frequency ranges. It is a particular problem on VHF when using the internal VHF converter. On 144 MHz the receiver�s effective noise figure probably increases by at least 10 dB while tuning. This is REALLY REALLY REALLY REALLY REALLY annoying, especially when trying to tune for very weak signals. I suspect that this problem may be inherent in step-tuned synthesized receivers. I wondered if there are any known mods or other methods for mitigating this problem. Would more front-end gain help? (That is, amplify the front-end noise more to override the noise generated by the LO.) I also wondered if the more expensive receivers such as Watkins-Johnson have this problem.

Thanks,

Lee, WA8YBT/6
Temecula, CA

I attended a forum at Dayton several years ago. I don't remember the name of the lecturer, but this guy was an antenna expert. He really knew his stuff. The forum I attended was on coax and other feedlines, and one subject he covered was this business of using an electrical half-wavelength feedline. He explained the several reasons why this really should be done, then quickly went through the calculations. What he found was that for all bands 10-80 there was a length that was a multiple of a half-wave, or close-enough to it. For a coax with a velocity factor of .66, that length is 91'3". This covers most common types of coax, but he recommended that you check the velocity factor when you buy your feedline, and scale the length accordingly. Since we are working with integer multiples of half a wavelength, you can cover 160 also just by doubling the length; in other words, 182'6", but you can't just cut it in half if you're not interested in 80m because not all the multiples are even; instead you must go through all the calculations again and I don't have my notes from that meeting. This was about 1988 or so, and I don't remember if he included the WARC bands in his calculations. I wish I knew who it was and some means of contacting him, because I'd really like to have that information again; I could kick myself for losing it.

Another thing that helps (I understand) is to connect a tuned counterpoise for each band of interest. This is nothing more than a quarter-wave of wire tied to the ground post of the radio and the rest strung up out of the way but more or less in a straight line. I've never tried it, but I have heard it helps a lot to get your radio at RF ground potential on the bands of interest. When you transmit, the counterpoise wires for bands other than the one you are operating on become detuned and have no effect.

Comments or corrections, anyone?

Message-ID: <31611A04.625A@ix.netcom.com>
Source record: 203478

I'm getting off 220, and am selling these rigs to pay for some
144/440 gear we're putting in here.

HT's:

KENWOOD TH-315A, very little use. With case, small charger, manual.
$225.00 plus shipping.

TEMPO S-2, a veteran, but works great. Thumbwheel freq.selection,
factory installed tone board, telescoping and rubber ducky
antennas, manuals, case. $175.00 plus shipping.

MOBILE RIGS:

Icom 37A, with mike/manual. Used mobile. Works fine except at temps
below 10F (squeals, etc. - a lot of rigs die of fright until car warms
up!!!) $225.00 plus shipping.

Kenwood 321A, tone, mic, manual, etc. used mobile but in excellent
shape. $300.00 plus shipping.

NOTE: This rig goes with the companion 221A for "stacking" for two
meters as well. The 221A is also available TO THE BUYER OF THE 321A
(NOT SEPARATELY!) with the stacking mount, for an additional $200.00.

Kenwood 3530A, toneboard installed, mic, manual, etc. never used mobile.
A really nice 220 rig, more elaborate than the 321A but bigger, so I
used this one in the shack. $325.00 plus shipping.

Most (I think all actually) of the rigs come with factory boxes and
all paperwork.

e-mail replies only pleez.......
Thanks!

>buildings and cars would also be lower than on 2 meters?

Just the reverse, actually. People seem to have a lot of
misunderstandings about "free path losses". The decrease
in signal strength with distance is purely geometric (depends
only on distance) and is *frequency invarient*.

Where people become confused is when the receiving antenna is
held constant with respect to *wavelength*, IE a 1/4-wave 1.2 GHz
antenna is much smaller than a 1/4-wave 144 MHz antenna. This
reduction in *capture area* scales inversely with the square of
frequency, so we see an *apparent* decrease in signal strength
with increasing frequency. But if we keep the antenna the *same
physical size* as frequency is increased, there is no increase
in apparent path loss. In fact apparent path loss is *less* as we
increase frequency.

And penetration into buildings and autos is *greater* as frequency
increases because the openings through which the signal enters the
structure become *larger* with respect to a wavelength. We've all
experienced this with AM/FM broadcast radios. The wavelength of
AM standard broadcast is so long that it has difficulty penetrating
a steel framed building, but the short VHF waves of FM broadcast
slip right through. The same thing applies even more to 1.2 GHz.

There is less refraction over terrain features as frequency increases,
but there is more scatter. So the location of coverage holes will be
different as frequency increases, but not necessarily better or worse.
Due to the increased scatter, multipath can be worse at higher frequencies,
not in absolute depth of fade but in the rapidity of picket fencing
for stations in motion. The tick,,,,tick,,,,tick,,,,tick of 2m picket
fencing becomes the tick,,tick,,tick of 70cm picket fencing and the
ti,ti,ti,ti,ti of 23cm picket fencing. It's actually less annoying.

The one area where higher frequencies suffer is in absorption by
foliage, wooden and masonary structures, etc. This does get worse
with increasing frequency. If you're at ground level trying to
communicate with someone else at ground level, and you're both in

dense forest, then a lower frequency will work better than a higher one.

What all this means is that if the repeater is well located on a high site, the users use antennas of reasonable physical size (IE a colinear 19 inches long for example), and the terrain is fairly open, then performance will be excellent at 1.2 GHz, very little different from 144 MHz in practice.

Does 30 years in broadcasting count? :-)

The big difference between broadcast or recording studio microphones
and communications microphones is the flatness and breadth of frequency
response. A communications microphone is designed to limit its response
to the 300-3,000 Hz span, and may have one or more peaks in the response
curve to aid intelligibility of speech. If you look at speech on an audio
spectrum analyzer, you'll find the energy confined to three relatively
narrow bands. The bulk of male speech energy is below 500 Hz, but carries
very little intelligence. You can discard most of it with no loss in
communications effectiveness. The energy in the 500-1000 Hz band and the
energy in the "fricative" 2,000-3000 Hz range carry most of the intelligence.
If you peak one or both of these, intelligibility improves at the expense
of "natural" sound.

OTOH, a broadcast or studio microphone has a wide span, 20-20,000 Hz,
and a very flat response curve. The goal is to be *transparent*, IE
high fidelity, so that what is reproduced at the other end is as identical
as possible to the sound picked up at the microphone. Of course it should
be obvious that *everything* from microphone to speaker *also* has to
have this broad and flat response for that to happen.

That's the rub with amateur operation. A SSB transmitter has a *sideband
filter* that's going to cut out everything outside of 300-3000 Hz, so it
doesn't matter if the microphone responds outside that range or not. And
the *modulation index* of a NBFM signal is going to reduce the frequencies
above 5 kHz so much that it's not worthwhile to consider a high fidelity
microphone there either.

Only with full plate modulated AM, or WBFM, can you get the channel
bandwidth to reproduce something approaching full fidelity audio. Even

then we only proof our broadcast systems from 20-15,000 Hz, and a standard AM receiver is going to cut that to 5,000 Hz in order to have adjacent channel selectivity. A standard FM broadcast receiver *can* pass our proof signal, so its fidelity will approach what we sent. A CD can do better, of course.

Now that just considers frequency response, to achieve high fidelity you also have to consider *dynamic range*. If your system doesn't track signal dymanics faithfully, IE if you use compression or you hit some clipping limit in the transmitter or receiver, then the fidelity will also be ruined. A CD has a dynamic range of some 90 db, but radio transmitters and receivers generally can't deal with that much dynamic range. The SPL (Sound Pressure Level) values of interest lie between 60 db spl and 100 db spl. At 100 db spl, we are crossing the threshold of pain, and 60 db spl is a whisper in a quiet living room. So 40 db of dynamic range is generally sufficient unless we're trying to reproduce a jet engine at takeoff thrust, or the proverbial pin dropping.

Now 40 db of dynamic range translates, for a 100 watt SSB transmitter, to a *linear* range from 0.01 watt to 100 watts. Only the *very* loudest transients should reach 100 watts, and the quietest breath sounds should fall around 10 mW. *Average* output power should be on the order of 8-12 watts for normal speech. Most hams would have a fit if the average output of their "100 watt" rig was only 10 watts, but that's what it takes to get the dynamic range for good fidelity. Audio engineers demand "headroom" in their amplifiers, and would have a fit if transient peaks actually ever reached the upper linear limits of their equipment, so they'd derate that "100 watt" transmitter even more.

Most communications receivers also lack sufficient dynamic range to reproduce a signal with high fidelity. Most would distort horribly trying to reproduce a transient peak equivalent to 100 db spl. They use AGC to try to keep signals within their dynamic limits, and that spoils fidelity too.

What this all boils down to is, if you want broadcast quality fidelity, you're going to have to use AM or WBFM modulation (or digitized speech, but we'll leave that as an application for the GRAPES 56 kb modem). If you're going to use SSB or NBFM, then a studio quality microphone is going to do you no good. The microphone is *not* the weak link in the chain. You *can* use a microphone with a tailored response, and/or a parametric equalizer, to *color* the sound to something pleasant to the ear, but it won't be high fidelity. And you can use a *good* compressor to tailor the dynamics to something that sounds pleasant to the ear, but it won't be high fidelity either. We call these methods "sweetening" in the broadcast and recording business. What we are trying to do is shove a silk purse through a sow's ear and make it come out not sounding like a bunch of oinks and squeals.

An ordinary consumer equalizer probably won't do for sweetening. And ordinary amateur speech compressors won't do either. You need a good

parametric equalizer, and ideally one that works dynamically, and you need a good compressor that has some intelligence so that it tailors its action to the frequency content of the signal at the moment. In broadcast, we use a box called the Optimod to do this tailoring at the transmitter, though we use a bunch of other expensive boxes in the studio to prep signals for later broadcast too. The engineer responsible for the station's "sound" can go nuts trying to get this setup to please the production people. They all think that they have "golden ears" when in fact an audio spectrum analyzer shows that most of them have ears of tin. :-(

If you want to experiment with a good microphone, I'd suggest the old faithful EV635A. There are more of them in use than just about anything else. They aren't the flattest, they cutoff around 12 kHz, and they have a proximity effect that can make you seem to have the voice of James Earl Jones when you really have a voice like Gilbert Gottfreid, but that's not terrible. And you can drive nails with one and it'll still work (remote pickup engineers really love that). And best of all for your purposes, they're cheap (by broadcast standards).

If you are running a plate modulated AM kilowatt, however, look around the back rooms of broadcast stations and recording studios and try to find an old RCA D77 ribbon microphone. They have such a mellow sound it could make you cry. Everybody will swear you're Mel Torme. Just don't ever bump it or it'll be needing a new ribbon.

It must be in excellent working order, and rediculously low prices would be appreciated. (I have a couple of friends who know these rigs inside out who will give me advice on whether the price is right--or better.) Please include a microphone and power supply if the total price will still be <= $250.

I'm trying to help out a retired (fixed-income) ham in San Francisco who really needs a rig. Thanks in advance for parting with your little-used gem!

76. FT8500 Audio Mute on Sub Channel

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-02 00:00:00 UTC
From: drm6@psu.edu
Message-ID: <drm6.63.3161851D@psu.edu>
Source record: 203483

Greetings to the group,

I am interested in buying the Yaesu FT8500 and have been following the review threads with interest. The issue of muting the audio on the 'sub channel' when there is activity on the 'main' channel has me concerned. According to the review threads, the 8500 does not have this feature as their HT the 51R has. I have a review copy of the manual for the 8500 with the new MH39 mic. On page 28 of the manual it discribes the 'Auto Receiver Mute" feature. The 'Auto Mute' function SEEMS to mute the sub channel (user selectable) when the main (also user selectable) is active. The other receiver mute function options do not seem to be of much use though.

Did Yaesu make a change in the 8500 to do this or am I not reading the manual correctly? I'm interested in the FS10 mic. Is this 'Auto Mute' feature on the 8500 with the FS10 mic? The copyright on the review copy of the manual I have is 1995 so it's conceivable that Yaesu added this feature to later rigs. Anybody know for sure? Does anyone have an 8500 that actually mutes the sub channel audio automaticly? Does Yaesu have an e-mail address for questions such as this? Any information would be appreciated. Thanks.

I want to send and receive data over a 2m simplex setup.
I want to use some Motorola portables and mobiles I have.
No need for "fast" rates or packet protocols. I just want
to do some simple telemetry; (temperature, servo control, etc.).

How do I interface my microcontrollers to the radios?
I don't want to use dtmf.

Any leads/help appreciated.

(I sure hope I got this constrained to AMD only!)

If you're a ham and you work at AMD, please read this!

We're starting an amateur radio club at AMD Austin. If you're in Austin, send me (or Curtis.Doss) e-mail for more info. We're just getting organized to ask AMD for space and support, so your interest is important.

If you're not in Austin, we'd like to know about any non-Austin AMD ham clubs (or hams, for that matter).

>Sundays, etc.)?

Look for that 735. The 728 is an entry level rig and doesn't compare well to the 735. Within some limitations, the new IC-706 is a fit successor to the old 735. Its receiver doesn't have the dynamic range, and it doesn't have transverter jacks, but it's not bad, and it does have some features the 735 doesn't, like a real narrow RTTY filter located where the RTTY tones *are* (you have to jack the IF shift all the way over to do RTTY on the 735), really small tuning steps for tweaking in a Clover signal, and it's so small you can't believe it puts out 100 watts. Having 6m and 2m doesn't hurt either. Of course it costs twice as much, but that's progress for you. It doesn't do QSK very well, though, and that might matter to you.

I can buy any radio I want (and have at one time or another, my latest toy *is* the IC-706), but none of them have displaced my IC-735 from its place of honor on the operating table. It replaced my Drake C line, and that's high praise indeed.

82. Kenwood Serial # s

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-02 00:00:00 UTC
From: rpmccoy@usa.pipeline.com
Message-ID: <4js06n$jjb@news1.h1.usa.pipeline.com>
Source record: 203489
Cross-posted to: rec.radio.amateur.equipment,

A question:

I frequently hear hams who are buying/selling
certain models refer to serial # ranges.
This typically applies to the 440S, 930S, 940S, etc.

Obviously, the higher serial numbers would
represent rigs with bug fixes and later manufacture.

Does anyone know what the "good" ranges are
for each series of radio? and why ?

Thanks for any assistance.

Dick, N4UN

Ya, but I bet you bought a decent duplexer with it. The 733 is
shipping with an Mighty Fine Junk (MFJ) duplexer. Some folks at HRO
tested it with a power down test and watched the device cause power
fluxuations as it got hot. The Diamond and Diawa they tested didn't.
They added it was like getting a Volkswagon muffler for your cadillac

>Jerry W4UKU flanders@groupz.net

I have to agree to a point.....HOME station equipment is likely covered by Homeowners...SO are HTs as they can be used both in the house and away... mobil gear is ALMOST never covered by HOME or CAR insurance and is best covered by ARRL or similar sponsored insurance (riders sometimes do not help on personal insurance packages)...

I lost ALL my gear in my Blazer last year during a break in....I had two Yeasu rigs (that were used at home...they had been to the shop being checked out and they were stolen during the return trip home while visiting some friends), a Standard HT, a cellphone (bag version) and CD player/ALL my CDs in a tote bag and my COMPANY's Toshiba 4600 laptop...

My insurance (State Farm) paid on the damage to the trunk and the CD player on my car insurance...the ham gear and cellphone were covered by homeowners...(at Replacement cost with a $250 deductible...wish it had been a $50 like the ARRL sponsored stuff! which I DO have at my rptr sites)...and alas, the laptop was covered by NEITHER (it wasnt MY laptop and they dont cover business equipment in a personal vehicle!...IF it had been parked on my driveway or property, they would have covered it but only to $2500...not the 4 grand it cost originally!)..

I got out of the deal about 1300 for all the RF gear and CDs that were stolen....considering it was well over 2100 original cost didnt help

any..

SO the moral is...
FIRST...make SURE you have receipts on EVERYTHING..or boxes or proof you own the gear for the insurance guys!

For gear used IN the house, your homeowners WILL cover it (check with your agent NOW! and get a replacement cost policy..it doesnt cost that much!)...

For gear used in the mobile ONLY (IE not an HT, etc), get the ARRL sponsored insurance....and maybe add an HT or whatever for a better deductible...

For gear that is NOT yours, either LEASE it (and have proof...) or get rid of it....and use the ARRL sponsored insurance....or similar...
The AHW insurance sponsored by ARRL does cover gear you lease (I have my company's IFR 1200s on my policy now...I "lease" it from my company..it made the premium DOUBLE....but its better than paying 8-9 GRAND for a new IFR!)

96. VHF - IMTS RadioTelephone 4sale

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-02 00:00:00 UTC
From: "Chris D. Johnston" <chris@netus.com>
Message-ID: <31622A77.73D8035@netus.com>
Source record: 203503

Well there...

How long has it been since any of you seen a private party ad for IMTS Radio Telephone equipment?

Well, here goes... I have a functional setup based on the Aerotron 600TT-60 transmitter (12 channel) and the Glenaire GL2000 control head. This is a VHF (hi-band) IMTS system that seems to work in California (well, used to 4 years ago), Nevada and Arizona.

The transmitter had been tweaked to 70W output. The GL2000 head can do pulse dial and supports both Mobile Telephone Service (MTS - Key up and get the operator) and Improved Mobile Telephone Service (IMTS - dial it yourself) modes.

I want $50 for it. I would consider donating it to a VERIFIED school group, HAM club or something. Whoever gets it pays for shipping. This antique (purchased new in 1981) cost me a $2200 or so. My how times change considering I dropped the same amount for my first Cell Phone.

Last I checked it still works. Complete with schematics for both control head and transmitter. Coverage maps for California.

Call me - Chris Johnston - 714-289-8543 days.

Anyone have a couple ASR-33 teletypes to trade?

Chris

97. Private Squelch mod for Motorola p10 radius

Hi Dave,

I also recently bought an FT530 (from the "local" HRO), as did a friend. I bought the Yaesu 12V car adaptor (for an outrageous $25!). My friend bought only a plug and cable for about $4 or $5. Both were purchased at the same store as the xcvrs. Call and ask the dealer you bought it from about the cable/plug. If they don't have it, call HRO - they definitely have them...

Good luck,

Scott N1WNO

>
>Rich
>N1VAJ

Every time it's happened to me it's been because the batteries were
not fully charged. Since the current drain during tx is several times higher
than rx, the voltage in a partially depleted battery can drop during high
current demand thus dimming the display. Keep your batteries charged and
your problem should disappear.

I assume you've already checked the xfrmr and bridges. There is one
resistoe that CONSISTENTLY burns out in some SB200s. Check R2 - a 10K
2 watt resistor. It might be the problem.

Hope it helps

>also studio-grade or special application units?

A stereo-type equalizer will work but it must have a microphone
preamp. Studio quality microphones are very expensive, new or used.
Considering the limited frequency response required for communications
work, it's my opinion that all of this is of only limited benefit.

>These guys always have booming signals with extremely real sounding
>audio. I cant go up another 100 ft, nor can I afford some of the amps
>out there, but this may be a feasable and fun place to really
>improve my station. Does anybody out there have any experience
>in this area?

The real sounding audio is more likely the result of being QRO than
anything else. Adding an amplifier increases the dynamic range of the
signal, and when it's really strong, the receiving station gets the
benefit of that. Also, to keep dynamic range high, the type of
operators you're referring to almost never use speech processing.

You could easily spend $300-600 for a used studio quality microphone
and a consumer-grade equalizer. However, for $350-500 you could buy
any of a number of good used amplifiers capable of delivering
750-1,000 watts. My advice is to buy the amplifier first. Then, if
you're not happy, pick up an equalizer or build a tone control
circuit. The latter is probably preferable, especially if it has a
separate control for bass, midrange and treble and is designed around
the communications audio range. Otherwise, you can end up with an
equalizer that affects only narrow bands of frequencies and which may
not have the control frequencies at the locations you need. Also, the
cheap ones (less than $300.00) can generate considerable ripple and
phase shift within the passband.

At any rate, once you've done all this, any remaining frequency
response irregularities will probably lie in the transmitter itself,
in which case a studio-quality mic won't help.

Incidentally, I've assumed the stations you mentioned were SSB or AM.
If they were FM, disregard all this. The dynamic range of FM signals
is limited primarily by bandwidth, not peak power capability.

73,
Jack WB3U

My HTX-212 will transmit from 143-149MHz. What I am wondering is: what is the difference between the HTX-212 and the 242? What new features are supposed to be on the 242?

124. Needed: 2 ea. 8873 power tubes

Hi, and thanks for reading this message.
A fellow ham of mine has recently bought a Henry linear which has both
of the tubes in need of replacement.
These are clamped to a heatsink with a BeO insulating block in between.
Anyone out there who wants to sell a couple of these tubes?
What price do you want?

Please e-mail me.

gary@ke4zv.atl.ga.us (Gary Coffman) wrote:

>People seem to have a lot of misunderstandings about "free path
>losses".

If anyone's interested, I have an Excel spreadsheet that calculates the received carrier/noise ratio at the receiver and plots it on a graph of distance VS dB. I designed it for commercial video transmission purposes, but the formulas and concepts are the same as for other modes. Parameters accepted by the spreadsheet are:

Transmitter power (watts)
Combiner/diplexer loss (dB)
Transmisison line loss (dB - or length and dB/100 feet)
Transmit antenna gain (dB)
Receive antenna gain (dBi)
Downconverter noise figure (dB)
Signal bandwidth (MHz)

The last parameter is used to calculate ENI (equivalent noise input) at the downconverter. Along the way, the sheet also displays EIRP in watts and dBm, as well as free space (path) loss. It assumes no obstructions in the path and 0.6 Fresnel clearance. I also have a second sheet that provides a visual representation of 0.6 Fresnel clearance for user-selectable frequency, distance, and transmit and receive antenna heights.

>And penetration into buildings and autos is *greater* as frequency
>increases because the openings through which the signal enters the
>structure become *larger* with respect to a wavelength.
<snip>

>one.

I haven't worked with signals at 1.2 GHz, but at 2.1 and 2.5-2.7 GHz, signal absorption is much more prominent than the increased penetration described earlier. Signals can easily be attenuated by 10 or 20 dB (or more) after entering a structure or passing through even a small stand of trees.

>I am looking at the Ten-Tec Scout for my first HF rig and I am interested in
>getting comments on and/or actual experiences, and opinions about this rig.

Hi Donn,

There has been much traffic on the group about this rig, and most responses
were very enthusastic. for quite little money you get a receiver wich is
much better than those of the low cost imports. The latter have a wide band
front end, and inductors tend to be very small and succeptible to saturation.

Gary is correct in mentioning that a s/h IC735 is a good alternative,
but buying a good s/h radio is another issue.

the new compact mobile rigs like the TS50 are surely "more radio" in that they
have 100W TX power and more knobs to play with.

good luck, 73, Moritz DL5UH

I looked all over trying to find Yaesu's "special" plug. Never found it! However, I ended up buying 2 of Yaesu's plugs (with about 3' of wire attached to each one) from one of the Seattle area ham stores for about $6 each. I attached them to high quality cig lighter plugs (from old radar detectors) with a FUSE. They work very well. So, I could have saved a lot of gasoline and time if I'd just bought the plugs from Yaesu in the first place. But, live and learn, learn, learn (and have FUN doing it). 73. Scott

Source record: 203380

Info and equipment wanted.

I'm planning to install a 928 Mhz link to a remote receiver for my UHF repeater. Does anyone have or can point me to some decent equipment for this task? I need a seperate receiver and transmitter. I want to cover a 10 mile shot between the two sites so I don't need lots of power.

I'm looking to beg, borrow, steal, buy and/or modify any equipment that is capable of operating on this frequency. I have a shortage of test equipment for this frequency range so repair/modification will be difficult but I will consider nearly anything.

Thanks. Post replies or email me directly.

Doubtful many shops would be willing to Flat Rate charge for repairs
on Amateur radio equipment due to the nature of the hobby. Owners
are likely to go into the radio and attempt repairs. many times
causing more damage then if they sent it to the factory. There are
other service centers that service ICOM equipment, you might ask at
75540.525@compuserve.com for a listing of authorized repair centers.
Malcom Technical Support in Colville, Wa is reasonably priced.

I think Pin 2 is 13.8 volts and I know Pin 3 goes to ground during
transmit. Attach a relay coil with a resistance of 150 ohms or mroe
for low current to Pins 2 and 3. now when you key the radio the relay
will close and the amplifier will key when attached to the normally
open contacts..

Forget it. Buy it from Yaesu or you won't have one. My experience has been
that there's only two places to find that size plug:

1. Yaesu
2. Japan

On the other hand, the folks at Yaesu are real friendly and helpful.

KAWIN NEWS

KaWin 6.37 is ready for download! Minor changes to the help file too.

The big news in version 6.37 will be a big yawn to registered KaWin users, but I'm hoping it will lighten the flames that periodically decorate my screen. ;-)

It starts with a new, kinder and gentler, nag meter. The new meter does not start running until the first time data is "sent" from KaWin. That means a prospective user can monitor indefinitely and explore the menus and features without the anxiety of that nasty old nag meter. Once it starts running, the new nag meter is purely time based, and visible, right at the top of the screen.

So, if you know someone who just couldn't get past the old nag meter to thoroughly evaluate KaWin, now's the time to try again.

Another assist for new users is an operator alert at program exit if a TNC that was opened in terminal mode is about to be closed in host mode. Host mode close remains the default - and, for good reason - but, TNC users who are new to host mode have been righteously incensed when their TNC fails to respond to their old terminal mode program after exiting from KaWin. This new feature should help.

Finally, KaWin has long been able to preserve the HF mode of a Kam from session to session as long as the Kam is not powered off, or if the Kam was closed in terminal mode. Now, that same capability has been extended to Host Mode close - even if the Kam is powered off between sessions.

All currently reported bugs are fixed in 6.37.

To add to the KaWin News mailing list, send email to stan@mutadv.com with the word SUBSCRIBE in the subject line, or use the handy subscription link on the KaWin Home Page. >Gee Monty,
>
>Often times a half wave of feeder is the LAST thing you want.
>
>What was the reason for such a strange conclusion?

When you are feeding a 50 ohm antenna system from a 50 ohm radio, with
50 ohm coax, minimum standing waves on the braid of your
coax (and thus minimum RF in the shack)
is achieved when the points at each end of the coax are current nodes. In
other words, there is a current node where the coax attaches to the radio,
optionally some others along the coax, and another current node at the
antenna feed point. Since current nodes occur at integer multiples of a
half wavelength down the coax, you want to choose your coax length so one
of them occurs at the end. Voltage nodes, on the other hand, occur at ODD
multiples of a QUARTER wavelength; in other words, halfway between the
current nodes. In the case of a tuned 50 ohm dipole, the ends of the
radiators are voltage nodes.

Choosing a feedline that's an electrical half wave (or multiple thereof)
not only reduces RF in the shack, but it also makes the SWR readings on
the shack wattmeter more accurately reflect what's going on out at the
antenna.

Someone correct me if I'm misremembering this. I guess y'all would
anyway?

No No No No No...

Cannot be done. No way, no how.

The 202 was PURPOSELY designed to receive 2 meter amateur frequencies ONLY -- that's why it has the tightest front-end on the market. If you want an expandable receive, you'll have to trade it for another brand -- and be willing to live with more intermod.

If you ever see a mod for a 202 to enpand RX or TX... here's a word of warning:

DON'T DO IT

Unless you want $200 worth of useless electronic parts, that is.

> jgoebel@rrnet.com

Jeff,
As I understand it, the rig covers only 430-440 - hence no US repeaters.
If anyone differs, please speak up! This is a nice price, but it still
seems too high for a radio with limited utility.

Nick,

I love the little radio! I've got an FT-10 with the '41 battery, and it's a marvel. The audio is great from the the radio itself and from Yaesu's optional speaker microphone. It sits very comfortably on your belt. I program mine without the optional software, and it's straightforward. I have to admit to "testing" it's durability on the first day I got it, and it suffered no damage from a four foot fall to the floor. With the RX Battery Saver mode turned on, the radio will run for almost a whole week on a single charged NiCd. Sorry to ramble, but I was just kinda thinking as I wrote...

Complaints? The "reverse SMA" antenna connector can be frustrating! I also use mine at the office with a "300 ohm J-pole" in the window and at home for an APRS station. Having to unscrew the duck, screw in the adapter, attach the BNC antenna connector, use the radio, disconnect the BNC, unscrew the adapter, and screw the rubber duck back in gets "tiring".

I've been *VERY* pleased with mine. If you buy one, I think you will be too.

<mwilson@bangate.compaq.com> writes:

>When you are feeding a 50 ohm antenna system from a 50 ohm radio, with
>50 ohm coax, minimum standing waves on the braid of your
>coax (and thus minimum RF in the shack)
>is achieved when the points at each end of the coax are current nodes.

No, that isn't true at all! Common mode currents (that cause RF in the
shack):

First, are they are not affected by the velocity factor of the cable. The
cable's internal dielectric has no effect on these currents! The
surroundings of the cable does have a great effect, and that varies with
cable placement. The use of the cable's published velocity factor in the
formula is completely without merit!

Second, a half wave of cable, or multiples (for common mode), is the WORSE
possible length imaginable to use with a half wave antenna. Unless you
WANT maximum RF in the shack! The ground connection at the shack reflects
as a low impedance for common mode currents at the antenna, and
maximum feedline common mode current occurs.

>other words, there is a current node where the coax attaches to the
radio,
>optionally some others along the coax, and another current node at the
>antenna feed point.

Feeding a half wave dipole, there will be a common mode current loop
(maxima) at the radio and at the antenna!

>half wavelength down the coax, you want to choose your coax length so one
>of them occurs at the end.

We really "want" the cable to present a very high impedance for common
mode currents at the sorce of the currents. That is at the antenna, or the
balanced to unbalanced junction. The highest impedance comes from using a
quarter wave of coax between a dipole antenna and rig.

Voltage nodes, on the other hand, occur at ODD
>multiples of a QUARTER wavelength; in other words, halfway between the
>current nodes. In the case of a tuned 50 ohm dipole, the ends of the
>radiators are voltage nodes.

The ends of the antennas are voltage maxima, not nodes. Node is the
minimum.

>Choosing a feedline that's an electrical half wave (or multiple thereof)
>not only reduces RF in the shack, but it also makes the SWR readings on
>the shack wattmeter more accurately reflect what's going on out at the
>antenna.

If the meter reads different SWR as it's moved along the line, either the meter or the line is of a different design impedance. If the meter's design impedance is 50 ohms, and the line design impedance is 50 ohms, the SWR reading will be correct and the same anywhere along the line (unless the line is very lossy).

Did a lecturer at Dayton actually say all of this without anyone questioning him?

>formula is completely without merit!

Well what he was using the velocity factor for was to determine what
PHYSICAL length of cable represented an ELECTRICAL half wave. In other
words, if you wanted a half wave length of feedline for six meters, you
can't just measure out three meters of coax; you first have to multiply
by the velocity factor. If you disagree with that, then you definitely
have a disagreement with this fellow, because I remember that part of
his presentation very distinctly.

>Second, a half wave of cable, or multiples (for common mode), is the WORSE
>possible length imaginable to use with a half wave antenna. Unless you
>WANT maximum RF in the shack! The ground connection at the shack reflects
>as a low impedance for common mode currents at the antenna, and
>**maximum** feedline common mode current occurs.

The ideal feedline is that which looks like there is no feedline at all;
in other words, the rig generating the RF signal appears to be right at
the antenna. Zero is an integer multiple of a half wave, but it is not
an odd multiple of a quarter wave.

If there is an error here, then it is only in my own mind and my memory
of the event. But I sure thought I heard "integer multiple of a half
wavelength," and I definitely heard 91'3".

>>other words, there is a current node where the coax attaches to the
>radio,
>>optionally some others along the coax, and another current node at the
>>antenna feed point.
>

>Feeding a half wave dipole, there will be a common mode current loop
>(maxima) at the radio and at the antenna!

I'm not talking about common mode and I'm not talking about differential mode. I'm not talking about loops, spins or dive bombs. All I'm saying is that in a properly designed feedline and antenna system, the RF current which flows from the radio, through the feedline, to the antenna, will be at a maximum at the radio and again at the antenna, and the voltage at these points will be a minimum.

I never said this stuff was gospel. I am, after all, doing this from memory and I'm just trying to impart it to the original poster as best I can. I did ask for corrections and comments. I guess the exclamation points were thrown in free of charge.

>>Choosing a feedline that's an electrical half wave (or multiple thereof)

>the line is very lossy).

A meter is only capable of reading what's going on at its terminals.

>Did a lecturer at Dayton actually say all of this without anyone
>questioning him?

Not just a lecturer, an antenna and feedline expert. No, apparently he did not say "all of this," he seems to have said something that I misremembered as being "all of this." No, he didn't lecture without questions. He took lots of questions, and answered them very satisfactorily.

Yours are the only comments I've received. I guess I'd better try and find this guy again. I'm trying to reproduce the computations now, for the 80m ham band. 468 / 3.5 (low end of 80m in Mhz) times a velocity factor of .66 gives 88 feet three inches. I wonder if the 91'3" could be close enough to this length for correct operation on 80m and the 3' difference was done to bring some other band into "close enough" range. However, the upper end of the band (for example 3.9 MHz) gives a length of 79'2".

It sure seemed convincing when I was sitting there.

I use the DSP 59+ almost exclusively on the digital modes, especially
nice during RTTY contests. Set the BP filter to 300-400hz and set the
center freq to 2120 (I think that's it, a special setting for RTTY)
and you can really isolate a signal in a cluttered environment!

Very nice piece of gear. For CW, setting the BP to 200-300hz and the
center freq to 800hz really lets you isolate weak cw signals too.

-->I don't have too much stuff -- just a few FM radios for voice and
-->computer networking. But, I lost a handheld last year while hiking!
-->An Alinco DJ-580T! I'll certainly tether my HT nicely while hiking
-->from now on, but a friend said that ARRL insurance covers accidently
-->like that, so I'm interested.

My experience was great. Had a dual band mobile and HT stolen from
my truck about 2 years ago. Had a check for ~$1,200 about a week after
they received my Police Report.

One thing to keep in mind. You only get the amount of money you claim
the item is worth. It is not really replacement coverage. In other words,
if your 3 year old dual band mobile is ripped off, you get what you itemized
it for, not what it costs to buy a new one. I update my itemization every
year. ($50 deductible applies).

So if you want to get $700 for that dual band radio if it is ripped off,
you need to insure it for $750. That costs 7.5 * $1.50 = $10.50/year.

RCA WT-100A and/or Hickok 700 tube tester wanted. Seeking unit in good running condition, needing some repairs or for parts (if I later come across a working unit). Willing to swap for something or please state a fair price for the respective unit. I would prefer swapping something as cash is tight, but I would have to find out what you are looking for -- I may have it. Please indicate if you have manuals, schematics, charts and/or plug-in tube sockets for the respective tube tester.

Kindly, email with details.

Thank you.

From: mikef@microtech.com
Message-ID: <4jsmlt$33k@news.aimnet.com>
Source record: 203510

A freind and I just purchased an old Measurements (Technology/Instruments) Model 59 grid dip meter. The problem is there isn't any documentation with the meter and we don't quite know how to use it. The biggest problem is that there isn't anywhere to attach the antenna.

Can someone shed some light on how this thing is supposed to work? I'd really appreciate some insight.

180. Commercial UHF OEM Transceiver modules WANTED

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-03 00:00:00 UTC
From: umbra@opennet.net.au
Message-ID: <4jsoj8$1r8@Tandem1.opennet.net.au>
Source record: 203511

I am working on an AVLS project in Asia that may require up
to several thousand units and I have been let down badly by a
supplier.

Actually, we are using a conventional VF transceiver in the
range 460-490 Mhz, up to 5 Watts FM. This is the 'let down' product.
Synthesized, 12.5 Khz steps programmable using jumpers or RS232
download of frequencies.

Can use a modified OEM board from a commercial hand-held transceiver.
Don't need speaker, mic, chassis etc. just the board.

Does Anybody manufacture or supply an equivalent radio ? We need it
to be about 100 x 90 x 20 mm (not including BNC female connector).

Our requirement is for 3000 units by 1 June 96.

This is as serious as a heart attack, because our supplier
was supposed to have 4 samples ready on the 8th of February.
As I type this, we are still looking at 3 weeks delay before
we get even the SAMPLES ! So basically we are crippled by the lack
of a suitable UHF radio.

Please get back to me at your convenience.

In article <4jq79f$c1v@Twain.MO.NET>, kninectf@mo.net@mail.mo.net says...

>Yes, with the extended receive mod the 10 meter module will copy 11 meter
>AM. The squelch works strange by you can get your traffic reports. You
>can also copy AM all the way down to 15 meters.

Whoa, what mod are you referring to? My 10M module will tune down there
(well, the DISPLAY shows I'm there, but I don't know if the PLL is locked)
but I'm unaware of any mod' which will switch in AM demodulation.

Incidentally, anyone else have RF feedback problems into their 10M module?
I can't have any 10M RF near the radio (like coming back down the shields
of the coax lines) or my transmitter locks up with a loud squeal.

I am studying for the Tech No-Code license and am looking for a portable
2 meter radio. What do I want to look for in a radio? Initially I would
like to use a portable between home and car. RS down the street has their
HTX-202, can anyone tell me if this is a good or bad unit? They also have a
model HTX-212 (mobile).
Is there an ideal or minimum number of memory channels to be had? I'm not
100% sure but I think the 202 puts out about 2 watts, right? That should be
more than enough for the local repeaters, right (Waldorf/LaPlata, MD area)?
Any suggestions are welcome.
Thanks.

-Dan.

I have a ft10, and, quite frankly, I wish I hadn't, it's useless in the city, where I work (London) because there is too much local RFI.

The main problem is not enough power, you'll need a 900ma or 1100ma 9.6v battery......

regards

Steve

> Lee, WA8YBT/6
> Temecula, CAFunny you should mention this, as I'm using a friend's Lowe Europafor a couple of weeks, and have found the same problem (also had the problem on my Lowe HF-150). Turns out that the receiver is radiating the hash and it is being picked up by the antenna. How do I know this? Simple...my ANC-4 nulls it out *completely*. It appears that the hash leaks out either the case, ot thru the power cable or the keypad cable. Whatever the path, if it were being picked up *inside* the radio, the ANC-4 in series with the antenna wouldn't have such a profound effect, IMHO.

Are you using a coax feed for the antenna? This will make a big difference, usually.

Walt

Kenwood TS-850S/AT wit auto antenna tuner, power cord, MC-60 micrhphone, and manual. Radio has some very minor scratches/footprints on top from where former owner had the DSP-100 sitting. There are some more noticeable marks on the bottom as a result of shipping when I bought the radio. The top marks are only noticeable in certain light. Front, sides, rear are in excellent condition. Ser. no. is 21 million. Radio works great. Display is brighter than newer units. Ship for $1,225.00. Also have DSP-100 with cables, and manual (copy). Several minor scratches on top. $230.00 shipped. Thanks, Jim...KQ4CS.

Let's see, I got my novice at 11, General at 12 with no outside help. I came from a very poor family (we didn't even have food half the time, let alone a TV set) and built my radios from parts scrounged at the dump. While my other friends were into booze and crime, I was sending CW.

Ham radio has always been the source of my education, and it certainly kept me out of trouble. I moved from well below the poverty line to a comfortable life, all due to stupid Ham radio.

I'm glad I viewed CW and theory as a challange, and not an obstruction.

On the other hand, I kind of agree with Nate. There's too little meaningful stuff anymore. I used to enjoy technical conversations, but I can't find them now. Was that one of your point's Nate, no interesting conversations?

From: n4lq@iglou.com
Message-ID: <DpBDIw.n10@iglou.com>
Source record: 203420

I picked up an MFJ 784B dsp filter Saturday at the hamfest. I was amazed at the results especially on cw. I first tried it on my IC-706. I followed the qsk up to 45 wpm without even connecting the ptt feature. Why even bother? The sidetone even sounds better now! Pure, smooth tone and so easy to listen to.

Tuning across a noisey 80 meter cw band, I found a signal buried in QRN. Pushing the (in) button, the signal lept from my speaker with a loud clear sound. Then pushing the (noise reduction) button, the QRN was instantly eliminated.

What I like about the MFJ is the ease of varying the different settings. Just turn a knob! Yes, it's a very flexible and effective tool.
BTW, hamfest prices can really beat normal dealer prices. I got this one for $50 off the list price.

Finally, MFJ has made a good impression on me. Nice work guys!

>..larry

The specs shows it has a lower power consumption (8A at 45W compared
to the 212's 9A), but I haven't checked that out yet. It has auto
memory scan to scan 144-148MHz and fill any unused memory channels
with the freqs it finds activity on. The biggest change is that you
can program into memory out of band freqs (one of the 212's missing
features). I bought one and am pretty pleased with it. I guess I
should say that I'm a RS manager, but when it comes to my personal
$$$, company loyalty is secondary and performace primary.

On the FT8500, auto mute seems to mean to automatically mute either the VHF or UHF channel (user selectable) when a signal is received on both at once. The mute does not seem to be based (unfortunately) on the band selected as the "sub" band. Oh well. I doubt very much if this depends on the microphone you select.

I have a pair of the 59's. You do not attach an antenna. The remote head contains a socket for the plug in coil set.This meter is FAR more sensitive than any other dipper. You can cut a 1/2 wave piece of wire and couple the coil to the current loop and see the dip! Try that w/ the MFJ and others.
I have the manual and if you will send an 8.5X11 SASE manilla envelope I will copy and forward.

Actually I was able to put together one in my local radio shack store. I bought a coiled "universal" adaptor which came with 4 plugs (all wrong) but was able to buy another pack of plugs in their "video game adaptor" section which included the one for the 530 - now I have a coiled adaptor with the right plug.

However, the works cost me about $12 (i have plenty of extra adaptors) and I find that on 440 I have had reports of noise in the signal while plugged in. Maybe the $25 for the "official" adaptor with a noise filter is not a bad deal.

I am using this one to power my 530 in the shack from a power supply with a cigar lighter adaptor.

: Actually, it has to do with an 18 year old who made the mistake of
: thinking this hobby had anything to offer someone my age. Maybe I should
: try ham radio again in 50 years when I truly have nothing better to do,
: and by then you won't need to know code.

Fair enough. I hope you can find something else interesting to do for those 50 years. Most hobbies have got their own equivalents of the perpetual code wars and the band full of hernia operation details. Perhaps you're just at the optimum age for seeing through things and suffer some shock and disillusionment at the exposed reality. This internet group seems to bring out the worst arguments in Amateur Radio, but you're quite right (in my opinion) about how uninteresting name, RST, QTH exchanges are, and how boring a lot of conversations are to people not of the same age group (this works *two* ways..)

Take a different field as an example: Do older people seem to be a bunch of old farts listening to ancient Pink Floyd, Elvis Presley or Mozart ? Do younger people than yourself seem to be a bunch of air-headed teeny boppers swooning over "Take That" ? Over the years, musicians have come and gone, but age group attitudes have been pretty similar. Now, how do *YOU* look to these two other age groups ?

There ARE people out there that you'd probably enjoy meeting, that share your interests and values. The trick is to find them. HF increases the geographical range that you can search over, though communication is more difficult than clear-channel work on VHF and via repeaters.

I'm interested in designing equipment, in doing things that haven't been done before, in pioneering new modes etc. I have to accept that *I* have to put some work into actively finding like-minded people, I have to accept that there are plenty of people out there that I would not like to meet, and I have to accept that some people wouldn't like to meet *ME*

By 18 I'd built myself a few receivers of progressively better performance, and had got through 3 generations of home-made oscilloscope. I was having fun, and I'd also laid the foundations (unintentionally!) of a career that now allows me the time and income to do most things that interest me. This was pure luck in my case, not judgement, not planning.

I'm no longer 18, but still remember what it was like. My interests and approaches have changed a bit, but we have both got to allow each other's age group to exist. I will not permit someone to force their hernia stories on me, nor will I allow myself to force the details of my latest measurements on an unwilling victim.

Have fun,
David GM4ZNX

Maybe he doesn't...

Ron, Many newsreaders have a facility where you can add a list of keywords or phrases to a file associated with a specific newsgroup. This list will be used to skip or discard topics or threads containing those keyword and phrases. Not as good as keeping uncivilised and uncouth individuals out of the newsgroup, but its better than nothing.

In my opinion, posting topics with title like the one in question to a public newsgroup (especially one whose topic is clearly technical and hobby oriented and not controversial in nature), is the same as going to a public place like your local shopping mall and shouting those words.

I would like to see the original writer of the topic, go to the shopping mall and repeatedly shout the topic of his note and see how long his free speach rights keep him from getting arrested or booted...

215. Can a cell phn be reprog to opp as a ham?

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-04 00:00:00 UTC
From: rpickeri@loyalistc.on.ca
Message-ID: <4k0hjd$2b3@knot.queensu.ca>
Source record: 203435

I would like to know if a cell phone can be altered so as to change the pll frequencies to get it to opperate in the 2m range.
I know cells opperate at about around 900mhz, with an IF around 40mhz.

Can a cell be re programed (along with a xtal change with the pll ref signal) so as to get it to opperate as a 2m ham radio?

I know a pll can be set to different ranges by a xtal change and different modulus numbers; however what conserns me are all the tuned circuits in the intial RF input and the output stage. If it can be done by reprogram the eprom in the phone and a few simple component changes I'd shure like to take a crak at it.

Please respond with any ideas or advice you can give!
Thanks

>
>Nate.

I got my license when I was 15, Nate. My son is 5 and can copy
CW at 10 WPM. It is just as exciting now as it was 20 years ago!
When I got my Novice there wasn't a no-code tech. If you would
get on the HF bands (for real) you would find it a bit more
exciting and challenging than 2 meter repeater operations.
But then maybe you don't want a challenge, you might just want
it handed to you like the last line of your comment suggests.
Although it probably isn't your fault that you want things handed
to you. Maybe you were brought up that way, expecting things
to be handed to you, not having to work for anything. Have your
"rights been violated" today? These are the two biggest problems
with many of the parents who themselves were raised in the sixties
and early seventies. They want more freedoms and rights. You
remember, "the sexual revolution." Rights were blurred with
licentiousness and now its their children who are doing the same
thing.
This actually belongs in a different group as someone else has
suggested so this is my last post on this to the group.

Hi Monty,
In article <DpAy46.HHA@twisto.eng.hou.compaq.com>, Monty Wilson
<mwilson@bangate.compaq.com> writes:

>Well what he was using the velocity factor for was to determine what
>PHYSICAL length of cable represented an ELECTRICAL half wave. In other
>words, if you wanted a half wave length of feedline for six meters, you
>can't just measure out three meters of coax; you first have to multiply
>by the velocity factor. If you disagree with that, then you definitely
>have a disagreement with this fellow, because I remember that part of
>his presentation very distinctly.

I agree with that *when* speaking of the desired normal transmission line
currents. But not at all when dealing with common mode currents that cause
RF in the shack! That formula doesn't work for unwanted ground currents.

>The ideal feedline is that which looks like there is no feedline at all;
>in other words, the rig generating the RF signal appears to be right at
>the antenna. Zero is an integer multiple of a half wave, but it is not
>an odd multiple of a quarter wave.

Sometimes having a certain feedline length is useful. The key is picking
the right length. In most cases a 1/4 wl (or odd 1/4 wl) line is best for
reducing RF in the shack. In most other cases, a 1/2 wl long feeder is
still the last thing we want. The issue is complex, but I'm sure this is
true in the vast majority of practical installations.

>If there is an error here, then it is only in my own mind and my memory
>of the event. But I sure thought I heard "integer multiple of a half
>wavelength," and I definitely heard 91'3".
>I'm not talking about common mode and I'm not talking about differential
>mode. I'm not talking about loops, spins or dive bombs. All I'm saying
is
>that in a properly designed feedline and antenna system, the RF current
which
>flows from the radio, through the feedline, to the antenna, will be at a
>maximum at the radio and again at the antenna, and the voltage at these
>points will be a minimum.

With a simple resonant 1/2 wl dipole fed with coax, the length of line
makes NO difference to "desired" currents. The current is essentially the
same everywhere on the line! The length of line only affects the undesired
common mode currents that cause RF in the shack.

>I never said this stuff was gospel. I am, after all, doing this from
>memory and I'm just trying to impart it to the original poster as best

>I can. I did ask for corrections and comments. I guess the exclamation
>points were thrown in free of charge.

Sorry about that. I wasn't being critical of you, I was extremely surprised a public speaker at Dayton could mislead people. The exclaimation points were to illustrate more than casual surprise, almost to the point of shock!

>>If the meter reads different SWR as it's moved along the line, either
the
>>meter or the line is of a different design impedance. If the meter's
>>design impedance is 50 ohms, and the line design impedance is 50 ohms,
the
>>SWR reading will be correct and the same anywhere along the line (unless
>>the line is very lossy).

>A meter is only capable of reading what's going on at its terminals.

The SWR is equal anywhere along the line. An SWR meter will read correctly at any location in the line. That information can be found in many sources, like the ARRL Antenna Handbook.

Methinks not. I wouldn't upgrade if I could send code str8key at 20000wpm.
I am saying that hf is LAME! Why would I want to be a part of it? I will
upgrade when I am 65+, and have nothing better to do. You may think that
everyone who doesn't upgrade is a lazy devil, and will not take the time
to learn to copy code... The problem is that I have much more important
things to do than sit in my basement & play with radios. I got the wrong
impression of ham radio, and that's why I got into it. I like
electronics, and all that jazz, but there is noone to talk to on HF that
talks about anything besides radios, etc. When I call someone on the
phone, we don't talk about what kind of telephone we are using.... same
thing. I am sick of hearing about everyones radio. (and all other boring
ragchew crap.) I listen to HF ALOT, and have worked alot too. I have
never heard anyone talk about Music, or Society, or anything interesting.

I have my opinions, you have yours. The difference is that I don't
automatically think my ideas are superior just because they are mine. I
am glad you like HF, but I DONT! (And I was half-hoping I could be
convinced otherwise before I totally gave up on Ham Radio.)

Nate.

I received a copy of an article which came from the University of Oregon. They have set up a wireless internet system on the University (One mile coverage) using 68 repeaters positioned around the facility. The computer uses an all in one modem radio with advertised speeds of 14.4 to 28.8. The company has set up simular systems in San Francisco.

Anyone hear about this or have any details. The name of the company is Metricom, Inc. and they are located in the San Jose area of California (408) 399-8200. I just wounder what it would take to establish a 28.8Kb link on 2m?

> KC8CGX

Doug,

I have used Code Quick and found it was a good way for me to learn code. It may not be the best way,
however.

It uses a kind of a word association and visual aid with the rhythm of the code. For example the letter r
is di-dah-dit, in Code Quick you are taught to associate the sound with the phrase brr-RAB-it (with
"brr and "it" representing the short sounds and "RAB" representing the long sounds) and a picture of a
shivering rabbit. Unfortunately, this could cause a problem when trying to copy code at higher speeds,
because the brain is trying to process to much stuff in a very short length of time.

All in all, if you are trying to learn code it may be one of the easiest and quickest ways. Recommended
if you are having trouble.

Good luck!

>right at the antenna.

I just caught the tailend of this discussion, but the preceding is not correct. What you're saying is that the impedance of the outside of the shield between the rig and antenna should be zero ohms. However, if that was the case, common mode current would be greatly encouraged to flow from the shield connection at the antenna through the transmitter chassis to ground. In fact, all else being equal, RF currents on the chassis of the transmitter would be higher than in any other possible scenario.

I enjoy HF projects and am looking for older junk radios and parts.

If you have a dead tube or SS TX RX or transceiver (up to about
1980 vintage) or just a pile O parts and want to get rid of them
then send me some email. I'm even interested in stuff that weighs
hundreds to thousands of lbs.....

I have surplus datacom, networking, and computer HW to trade.
Can also trade technical help with mods or repairs to older
radios.

Also available for trade.
BC669 top section only.
All tubes there, no meter, rough.
Aircraft Radio corp R32, 108-135MHz RX.
no dynamotor, missing top and bottom covers, missing 2 x 9 pin tubes.
Appears to be otherwise unmolested.
Decibel Products remote antenna monitoring system, new surplus
with a number of (7) vHF and UHF directional couplers.
Sun SLC workstation. (SPARC)
Sun IPC workstation.
Sun 4300 board in 4110 chassis.

>on fast foods, in apartments, with nothing paid for, and nothing elce to
>do but call us old farts smelly.
>
>Jim, WA7NDD

Amen to that Jim! He's just jealous that's all. He's a no-code
tech licensed in October 1995 who has probably never been on HF anyway.
According to his email information and FCC callsign information he is:

KB9LSX GINGRAS, NATHAN R LIC ISU 12-OCT-1995
TECH 3653 E PLANKINTON LIC EXP 12-OCT-2005
DOB 15-JUL-1977 CUDAHY WI 53110 LST UPD 12-OCT-1995

He's crying about the 20WPM code test. That hasn't gotten any
harder over the years it's gotten easier. You used to have to
copy a solid minute correct, now you only have to answer 7 of 10
questions about the QSO correctly. He would have no trouble getting
the 20WPM code or the theory that went with it if he'd spend half
the time studying it that he spent maligning it! If they continue
to live on the fast foods and fast money they may never live to be
an old fart. My grandfather was 5HS, later to become W5HS. He was
a ham for 60 years and was proud to be called an old fart. He was
also called an "Elmer" by many. Maybe that's what Nathan needs,
a good Elmer to guide him (or kick him in the a**.)

I've heard it said that you can re-tune celphones up to the 902 MHz ham band, but I've never had a working celphone with documentation to try this out.

If you know a good way to disable the frequency-hopping functions, and allow manually setting the transmit and receive frequencies through the keypad, TELL US NOW!!!!! Even if it's just for one style of celphone. Even if it'll only do one frequency on simplex.

Even if it has to be hard-wired inside for single-channel simplex operation.

As far as conversion to 2 meters, no, it's not feasible unless you set up a phone patch from your celphone to a 2 meter rig. And this would defeat the purpose of what you want to do.

250. More on FT-530 mods

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-05 00:00:00 UTC
From: Dave Fifield <fifield@lan.nsc.com>
Message-ID: <31657ACA.2778@lan.nsc.com>
Source record: 203270

I have a brand new FT-530. I did the "green wire" mod. It does NOT receive on the 800 to 950 MHz band.

A friend of mine also has an FT-530 that he bought last year. He also did the "green wire" mod. His radio DOES receive stuff on 800 to 900 MHz.

Both radios have exactly the same schematic (I borrowed his to check).

Soooooo, that leads me to believe that the ONLY difference is in the control module programming. Checking the circuit diagram, there is a signal (L1) that could control the RX front end power. Maybe this gets turned off? I'll check.

Maybe all "we" need to do is change one of the other little links? Anyone found out anything else yet? Anyone got a proper service manual yet?

Let me know, thanks.

Email fails to your address, so I'll offer a suggestion here.
Look at the TEKK KS-900. It fits your power and size constraints
fairly well, and is intended for board mounting. It's designed as
a data radio, used here for 9600 baud, runs 2 watts, and can be
crystalled anywhere in the UHF band. 800-521-TEKK is their number.
(I know that's no good internationally, but it's all I have.)

Need a basic HF rig and/or want to be ready for the 6 meter
Sporadic E season ahead, then you may be interested in the
following:

Kenwood TS-680S HF/6M Transceiver
100W all HF bands 160M-10M (incl WARC), 10W 6M
Receives 500 kHz - 35 MHz, 45 - 60 MHz

Includes the following optional items:
YG-455C-1 500 Hz CW filter
IF-10C rig control interface
j-com RS-232 converter cable (like IF-232C)
MB-430 mobile mount
SP-430 external speaker
Service Manual

One owner, non-smoker
Electrically excellent (never needed service, only mod to restore
AM BC sensitivity)
Cosmetically very good (some paint wear around power control
slider and top front corners)
Includes original packaging, owner's manual, hand mike

$775, includes UPS shipping

Hmmm... my IC-2000H is quite good. It is nearly as good as a Motorola
MCX-100, at least in my experience. I've been to several heavily
populated radio sites with it, and it seemed to do an excellent job
of coping with dozens of high powered VHF high band transmitters.

Sounds like you may have a broken radio...

Jeff,

I think the 720A has a low band antenna input for operation below 1.6
Mhz. This was quite common in ICOM H.F. radios of that vintage. So an
antenna connected to the usual antenna connector will do nothing got
below 1.6 Mhz.

Source record: 203278

OK, I see the problem with this thread now. There are too many Dayton Experts and not enough plain folk. As always, comments, criticisms and nit-picking are all equally welcome.

1. Creating Current In The Coax

When the transmitter places an RF voltage on the center conductor of the coaxial cable, RF current flows into the center conductor and sets up a circumferential magnetic field. The rise and fall of this field creates an equal and opposite current on the inside of the shield. The relationship between these two currents is fixed by the nature in which they interact inside the coax and nothing external to the cable will change this. The current on the center conductor and the current on the inner shield will always be equal and opposite.

2. Current Flow To The Load

The equal and opposite currents in the coax flow toward the load at a speed determined by the velocity factor of the coax.

At the point where the coax ends at the antenna, the magnetic field that maintains the equal and opposite relationship inside the cable collapses. Both the inner conductor and the inside of the shield simply become two wires carrying equal and opposite RF current. Each wire also has an equal and opposite RF voltage, although the voltage may not be in phase with the current. The voltage on each conductor is electrically attracted to the load, to ground, and to the voltage on the opposite conductor.

3. Where Is The Load?

The current on the wire leading from the center conductor of the coax to the dipole has only one path - the leg of the dipole. Current on the other wire, leading from the inner shield of the coax, has two paths. The first path is the leg of the dipole to which it's connected. The other is the outer surface of the shield of the coax.

For RF purposes, the outside of the shield is an unwanted conductor that's attached to one leg of the dipole. To visualize this a little better, remember that skin effect causes RF to flow only on the surface of a conductor. As a result, the shield is actually two separate conductors at RF - the inner surface and the outer surface. These two conductors are joined together at each end, but elsewhere they are isolated for RF.

4. The Path To Ground

Current flowing out of the inner shield at the antenna will take two paths. Part of the current will flow onto the leg of the dipole and part will flow down the outside of the coax toward the hamshack. The current flowing on the outside of the shield radiates and it will continue to radiate all the way into the shack. Once it reaches the shack, it seeks ground through the chassis of the transmitter, as well as anything the transmitter is attached to (including other equipment and the AC line). This creates RF current flow on equipment grounds and accessories. Depending on the exact nature of the situation, this can burn the operator, cause equipment malfunctions, and generate RFI.

5. The Balun Solution

A voltage balun at the antenna creates a magnetic field within its windings that tightly couples the energy exiting the coax. This coupling overcomes the attraction to ground for currents that would otherwise travel down the outside of the shield. A small current may continue to flow on the outer shield following installation of the balun, but unless the impedance to ground is very low, it will not be significant.

A current balun provides much the same function, but by different means. The current balun acts as a large RF choke on the outer shield, isolating the shield as a potential current path. This forces nearly all the current to flow out to the leg of the dipole, reducing outer shield current to a minimal value.

6. SWR

Any mismatch between the impedance of the antenna and the characteristic impedance (Z0) of the transmission line will create reflected waves and cause SWR to rise above 1:1.

SWR is typically measured by the ratio of forward current to reflected current. Current is the same everywhere in a series circuit, therefore the forward current and reflected current are the same everywhere in the line. This means that SWR is the same everywhere in the line, and that changing the line length will not change SWR. If an SWR meter indicates a different ratio when line length is changed, the possible causes are A) the meter is imperfect and is being affected by other conditions, B) the meter employs a technique that consists of something other than pure current measurement, or C) current flowing on the outside of the shield is sufficient to render the outer shield a part of the antenna (thus changing the length of the coax actually changes the antenna length).

The latter does not mean that SWR varies within the coax, only that changing the length of the shield has affected the impedance at the feedpoint of the dipole. Unfortunately, it is not possible to change the internal path length without also changing the length of the shield. Therefore, a cursory observation of this phenomenon often leads the user to an incorrect conclusion.

7. Impedance

When SWR is 1:1, the operational impedance (E/I) will be the same throughout the line and will equal the Z0 of the line. However, SWR causes the operational impedance to change throughout the line because the reflected current is not in phase with forward current (this is what creates standing waves). At the location in the line at which the forward and reflected currents cancel each other, a current minimum (node) exists and impedance will be high. Where they become additive, a current maximum (loop) exists and impedance will be low. Between the current nodes and loops, impedance will be at some median value.

Because impedance changes throughout the line, changing the length of the transmission line will cause the impedance seen by the transmitter to also change. The exact impedance will depend on the relationship of forward and reflected current (and voltage) at the point at which the transmitter is connected. It should be noted that this change in impedance is often misinterpreted as a change in SWR, because some SWR meters use an internal reference set to 50 ohms.

8. Coax length

If the transmission line is an exact electrical half wavelength (or multiple) at the frequency of operation, forward and reflected current will coincide at the input of the line in such a way as to duplicate the impedance of the load at that point. This is useful if the antenna presents the desired load for the transmitter, because the antenna's impedance can be made to appear at the input of the line regardless of SWR or the characteristic impedance of the line.

If the transmission line is an exact electrical quarter wavelength (or odd multiple) at the frequency of operation, forward and reflected current will coincide at the input of the line in such a way as to create the highest possible impedance at that point. This is useful if it is desired to isolate a signal source from a particular load at a particular frequency.

In order to achieve a specific electrical line length, the velocity factor of the transmission line must be taken into account.

9. Shield length

The most appropriate shield length is usually an electrical quarter wavelength (or odd multiple) at the frequency of operation. This will provide maximum isolation between the junction of the coax shield and antenna, and the transmitter. However, this may change if the antenna isn't resonant because standing waves on the antenna itself will move the current loop away from the feedpoint.

Conductors attached to the outer shield at the transmitter may also need to be accounted for. Multiple conductor lengths are usually involved and the impedance of these conductors to earth ground or to other electrical mass may be difficult to define. Standing waves may also be created on the shield. The many unknowns that result from factors such as these, and the difficulty in analyzing them, may

combine to render the quarter wavelength shield less than effective.

Note that velocity factor applies only to currents subjected to the internal structure of the coax and is not a modifying influence in the length of the shield. A side effect of this phenomenon is that it is not possible for a given length of coax to have the same electrical length internally as on the shield.

10. Non-resonant Antennas

If the antenna is not resonant, reflected waves on the antenna itself will alter the relationship between the physical length of the outer shield and its ability to isolate antenna current from ground. In addition, the amplitude of standing waves may be very high, causing the symptoms to become more obvious. This often leads to the conclusion that SWR causes RF in the shack, when in fact it has merely aggravated a preexising deficiency of the system.

11. Non-Resonant Antennas And Baluns

As mentined previously, the balun provides a solution to the problem of outer shield current. However, when faced with a high impedance load such as a non-resonant antenna, a balun may cease to function as intended. When this occurs, RF current may bypass the balun in favor of the outer shield, again causing noticeable RF in the shack. This condition often reinforces the erroneous concept that SWR causes RF in the shack, although it is only indirectly related. If the system is used for multiband appications, the solution is to either utilize a resonant antenna or find a means other than a balun to maintain system balance. Once the problem is resolved, grounds in the hamshack should be RF free even if an earth ground is not attached.

Hi Mike...Tom is on the right track...and I'll toss in my experience
too. The diodes in the stack get leaky as they age (from heat)
and will start passing more and more AC component as time goes]
on. Just for grins, you can replace the diodes in the stack for about
$3 apiece and that'll give you a point to start with. This is all
assuming the multiplier resistor is good...an ohmeter can help there.

Good luck

Doug, K7YD

Since the only currents (or voltages) that can result in RF in the
shack syndrome *must* flow on the *outside* of the coax, velocity
factor for currents flowing *inside* the coax is irrelevant. The
VF for currents on the outside of the coax is the same as if the
currents were flowing on an ordinary insulated wire, and at HF that
is roughly equivalent to the free space length.

>>Second, a half wave of cable, or multiples (for common mode), is the WORSE

>wavelength," and I definitely heard 91'3".

There's an error here all right. The error is in confusing behavior of
currents on the *inside* of the coax with behavior of currents on the
outside of the coax. In a matched system, IE 50 ohm transmitter, 50
ohm coax, and 50 ohm antenna, there are *no* net return currents down the
inside of the coax, IE SWR = 1:1 and all power flows unidirectionally
to the load, *regardless* of feedline length. If the coax is terminated
in a mismatched load, say 75 ohm antenna feed impedance instead of 50 ohms,
then the SWR on the coax won't be 1:1, there will be reflections down the
inside of the coax, and the transmitter will see a load impedance other
than 50 ohms.

A swing around the Smith Chart will show that this load will appear higher
or lower in impedance than 75 ohms at the transmitter depending on the
particular line length. At the "magic" length of 1/2-wave (internal to
the coax including VF) the load impedance repeats, and the transmitter
sees 75 ohms, which is still a mismatch. The transmitter has to be adjusted
to match this presented impedance, and when it is, all *net* power once
again flows unidirectionally to the load and is dissipated there.
Now this is key, the *same* thing happens at any other coax length.
As long as the transmitter is tuned to match the presented impedance
(whatever it is), all net power flows unidirectionally to the load.
No power can escape the coax except at the antenna load, and there is
no hot shack.

It may well be, and often *is*, easier to match the impedance presented
at the transmitter end of the coax when the line length is something
other than 1/2-wave. An example of that is when the antenna is a full
wave at the frequency of interest and the antenna impedance is thousands
of ohms, IE a 80m dipole used on 40m. A length nearer a 1/4-wave in that
case will serve to transform the presented impedance to the transmitter
down to something fairly close to 50 ohms, and thus easier for the
transmitter to match.

>>>other words, there is a current node where the coax attaches to the

>flows from the radio, through the feedline, to the antenna, will be at a
>maximum at the radio and again at the antenna, and the voltage at these

>points will be a minimum.

Inside the coax. But that's irrelevant as long as the transmitter
can drive the presented impedance. The only voltages and currents that
matter to the hot shack syndrome are those on the *outside* of the
coax. Coax is *balanced* line. The currents on the inner conductor
are balanced by the currents on the inside of the outer conductor.
That's why coax doesn't radiate. At the antenna, if you don't use
a choke "balun", currents from the inside of the coax outer can "turn
the corner" and flow back down the *outside* of the coax (dividing
with the currents flowing onto one half of the dipole) while currents
on the inner flow out completely onto the other half of the dipole.
This current flowing back down the *outside* of the coax is *unbalanced*
because the current that could have balanced it is flowing on the antenna
instead. Therefore this current can radiate, and can propagate down the
outside of the coax back to the shack and make it hot to RF.

A 1/2-wave wire is naturally resonant, and will have a voltage *maxima*
at its ends, regardless of whether it is excited in the middle or on
one of its ends. In fact, if it is excited at one of its ends, the
impedance presented will be thousands of ohms. That's why the fellow
at Dayton was right, and Tom is wrong. Because the end of the coax
outer looks like thousands of ohms when it is a 1/2-wave *physical*
length. The currents at the antenna will divide unequally with most
of the current flowing into the low impedance of the 1/4-wave half
of the dipole, and very little trying to turn the corner and flow
into the high impedance presented by the coax outer end.

Tom's mistake is trying to use transmission line theory on what is *not*
at this point functioning as a transmission line. It is, instead, an
unintended end fed 1/2-wave antenna. Now while it is true that the
ends of such an antenna are voltage maxima, that's because the ends
are very high impedances, and thus not much current will "turn the
corner" to excite this "antenna", so there won't be much high voltage
down at the shack end. OTOH, a 1/4-wave will be a low feed impedance
at the antenna, thus lots of current will divert down toward the shack,
and will express itself as a high voltage at the high impedance of the
other end. (And the other end *will* be a high impedance because the
current can't penetrate the coax shield or the transmitter case to
"close the loop" with the driving source. Whether the transmitter case
is connected to Earth or not is largely irrelevant as well.)

>
>A meter is only capable of reading what's going on at its terminals.

Right, and its terminals are connected *inside* the line segment
internal to the SWR bridge. That's 50 ohms, if the line is 50 ohms,
the meter will read the same regardless of where in the line it is
located. The fact that there may be RF flowing on the *outside* of
the line section will have no effect on the meter reading (assuming
the meter is properly built). The critical factor to remember is that
the coax outer is a Faraday shield, currents can't pass in or out,
so they don't interact at all except at places where the shield is
broken (such as at the antenna feed point) and they can "turn the
corner".

I'm sure Tom is having cats and little kittens at this point. :-)
This is not how he would analyze how coax works. That's Ok,
models are just tools for visualizing what we measure. This
model works, so does his (when applied correctly), I just find
this one easier to visualize.

Well now you have a second voice. Your expert was right (sort of) but
for the wrong reasons. Tom is (mostly) right but also (sort of) wrong
for the wrong reasons in saying a 1/2-wave line gives the "hottest shack".
Actually, it is the 1/4-wave that gives the hottest shack if currents
are allowed to "turn the corner" at the antenna feed point. If they
aren't (by use of a choke "balun") then neither will cause a "hot
shack" and line length is irrelevant to the issue.

(I'd suggest we dispense with the term "balun" here and simply refer
to this as a RF choke since that's the function it is actually performing,

IE choking off currents on the *outside* of the coax.)

>73,
>Jack WB3U

That's assuming the currents are flowing to "ground", Jack. But
that's not what they do. The current is trying to "close the
loop" back to the source, Kirchhoff's law, and the source is
inside a Faraday box called a transmitter. The RF currents on
the outside of that box can't get in, can't close the loop,
and therefore that model fails. The currents flowing on the
outside of the coax and transmitter enclosure are *antenna*
currents, unintended antenna to be sure, and the only way they
can dissipate is by radiating. "Grounding" the transmitter only
gives the currents a bigger "antenna" to flow over.

>The radio club is looking for a NEW service monitor.
>
>Spending $5,000 or so, what do you recommend???

Saving up lots more money. :-)

There aren't any good NEW service monitors for $5,000. The cheapest NEW service monitor that's worth owning is $9,000, the IFR500A, and the better ones run twice that.

You could get a *used* IFR1200 though. And that would be a great instrument. I've seen them for sale for as little as $3,500 to $4,000. Spend another $750 to have it checked, calibrated, and certified by the IFR factory, and you'll have a real gem. Not as nice as a new IFR1500 with tracking generator, of course, but still a fine instrument, and not $18,000 either.

Of course a Motorola 2001 could be made to suffice in a pinch too, but you *won't* want to carry it to the repeater site. It's bulky and heavy, yet fragile.

>all of my memorys and other settings. I think my lithium battery is dead.
>The instruction manual says to send it back to Kenwood to have the battery replaced.

Devon: I replaced the lithium in my TM-221 2M radio (very similar to
TM-231 I'm sure). It is located in the front panel assembly, and can
be replaced if very careful going about it. Battery is a standard
type, but difficult to find with the necessary tabs. I removed the
tabs from the old battery, and VERY CAREFULLY soldered them onto a new
battery. Other than this soldering process, it is a very simple
disassembly process. If you need more info, I can provide it.

IF YOU ARE IN THE LEAST UNSURE ABOUT DOING THIS, HAVE KENWOOD DO IT.
SOLDERING LITHIUM BATTERIES CAN BE VERY DANGEROUS. As they say, you
shouldn't try this at home hi hi.

No, you can't get the cellphone down to 2m. It's possible you could
move it to the 902 MHz amateur band, however. The split is wider than
that band, though, so you won't be able to use it duplex. Getting it
to work simplex, or at least on a short split, would be challenging,
and the output bricks in those things usually don't work well in the
902 band. The modules are potted, and there's no access to the frequency
determining elements of the hybrid. Probably the best thing to do with
one is to use it for parts. There's some neat stuff in there that you
can use in a homebrew rig.

Many of the older cellphones could be put into service mode from
the keypad, my Uniden can be. That allows you to set the transmit
and receive frequencies, put it in transmit or receive manually,
run the power up and down, etc. It will *not* allow you to work
simplex, however, because transmit and receive bands are offset
by 45 MHz and you can't change that.

With all the illegal cloning going on, newer phones generally can't
be put into service mode without a special factory jig and special
software that the factories don't let out of their sight.

> IMHO.

On the R8 and R8A, this is not leakage, it is phase discontinuties
in the frequency synthesizer. The R8 synthesizer operates in base
100, with different PLL's handling tens of Hz, thousands of Hz,
and hundreds of kHz. When you tune from, say, 5.00099 to 5.00100
MHz, the 10 Hz loop drops down 990 Hz while the 1 kHz loop jumps
up 1000 Hz. These jumps are neither instantaneous nor simultaneous,
so for a couple of milliseconds the receiver is mistuned by hundreds
of Hz. I've actually measured the phase discontinuity on my R8:
it's about 8 radians.

I'm trying to use the R8A for a satellite data collection project,
using it to feed narrow band CPFSK to a software demodulator.
Doppler tracking of the spacecraft carrier (by commanding the R8A
from the computer) causes a phase discontinuity, and thus a possible
data dropout, every kHz. This is more a minor annoyance than a
major problem (but I'm still annoyed :-(. I also have a few $10,000
telemetry receivers for this purpose, but at low signal/noise they
show a much higher bit error rate than the R8A/software demodulator
combination (and are too expensive for a big network anyway).

There are also some extremely faint clicks on the 10 Hz boundary,
but I need a very clean, high signal/noise carrier to hear them at
all, and I can't find them with my phase tracking software.

I have a Kenwood TS-50 plus its antenna tunner AT-50 for sale starting
today, $1100. Need money to buy a house.

Because I live in an apartment I have not been able to set up my antenna
R7 which I'm also selling for $280.

Only used it 2 times for testing, Mint condition.
I'm a computer engineer and I can assure you this radio is mint!
I have boxes and manuals for every gear, and antenna.

First person with a check keeps it.

Sorry, it's late. On second thought, when the PTT is pressed and the display starts to fade, that is the END. No more battery life. If you're getting normal operation after this I'd send it back to Kennwood.

>after month.
>
>73

That's why I wired in a group of relays. I have them timed to move
sections of wire along the same direction as the electron flow.

It's sorta like picking up part of the river in a barge and transporting
it downstream on a very fast jet.

If you zig zag a number 8 wire (the electrons move real slow in it) and
keep the relays close together, you can really speed up the electrons.
When I get em going really fast I feed them into a wire with a gradual
taper and that accelerates em like a hose nozzel.

After they're going fast, I shoot em up my feedline. That's better than
having em just sitting there jiggling around.

304. Need help with high SWR problem

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-05 00:00:00 UTC
From: Ron Thompson <ron.thompson@bglobal.com>
Message-ID: <4k3dk9$5mg@lambchop>
Source record: 203355

I have a mobile 2M 50W radio I am using as a base rig.
It runs off of a 20A power supply, and feeds a 75 foot
piece of RG-213 connected to a Cushman Ringo Ranger II
7db gain antenna.

When I adjusted the tuning rod, my SWR meter was hooked
up near the radio. I got the SWR down to 1.1:1, but the
indicated forward RF power was 120 Watts. This radio
only puts out 50 Watts.

In use, the radio can recieve another 50W radio, but
cannot transmit to it very far. This indicates to me
that all the power is not getting out.

I then moved the SWR meter to the antenna end of the
feedline, and took another reading. The SWR was
over 8:1, and the indicated RF power was about 50 Watts.

I unscrewed the shield from the feedline on receive to
see if there was a short, but the signal dropped. I
also used a multimeter to check for a short between the
shield and the center wire, and it is OK.

This is the second antenna I have tried, since I thought
something was wrong with the first one. Same thing
with both antennas, so I can rule that out.

I'm stumped. HELP!

Please e-mail reply as well as posting.

>Boy, did this guy just fall off the turnip truck today? Or was he
>born yesterday? What a stupid question!
>
There aren't any stupid questions, just stupid answers. The original poster exhibited quite a bit more knowledge about what goes on inside a cell phone than many people you'll hear on the air or read here. With quite a few of the older trunk-mounted cellphones showing up surplus for very low prices, it is a natural question to ask if they can be used for ham radio. They are also usually very solidly built (for consumer products anyway).

The short answer is that it isn't practical to try and convert a cellphone for 2m use. The oscillators, front end, and power amplifer would all need to be replaced. Only the IF and synthesizer sections would be of much use, and the bandwidth of the IF is 30 KHz, not the 12 or so that is usually used for narrow-band FM in the 2m band. (Back when cellular was first designed, it was decided to trade wider bandwidth for better voice quality. The 800 MHz band seemed infinite).

The band to try and convert to would be 902-928 MHz. But this is complicated by the phone's design for full duplex (receiver operates 870-895 MHz, transmitter always exactly 45 MHz lower). There is a duplexer that combines the two to the antenna terminal, this part is probably only useful for the cellular band so it would need to be removed. In some cases there are separate transmit and receive oscillators, in others the transmitter oscillator is the LO for the receiver. The receiver willprobalby tweak up to the low to middle portion of the 900 MHz band, butthe transmitter may not work very well there. Since there isn't 45 MHz of space there for full-duplex operation, the single-oscillator design will have to retune 45 MHz between transmit and receive.

The control logic would have to be redone as well, since it won't do anything without instructions from the cell site. It is fairly straightforward for testing purposes to load the PLL chip directly from a port on a PC. Usually the PLL setup is general-purpose enough that changing the crystal is not required.

If the decision is made to scrap it rather than put it on the air, there are some interesting, educational, and useful parts inside a cellphone. The PLL section is usually a "textbook example" already built with good stable components. The IF section is wideband enough for 19.2 Kbaud FSK, and a data seperator is included (cellular control data is Manchester coded at 10 Kbps). The audio path contains a 2:1 compressor and expander as well as tight 3 KHz active filters. These may be useful as part of other homebrew radios.

: born yesterday? What a stupid question!

Perfect opportunity to educate him and you slagged him. What a wizard
you are, J.W.

Robin, the biggest problem you're going to run into isn't reprogramming
the PLL in the cell phone to work in the 2 meter band. You'll virtually
have to re-engineer the phone to make it work. All the tuned circuits in
the transmitter and the receiver up to the first mixer are at 800 MHz and
the transistors and ICs are designed to work at that frequency as well.
Cell phones also have control mechanisms tied into the PLL that'll have
to be converted so the radio doesn't start looking for the new cell site
when the SNR drops. You'll also have to add some basic controls such as
volume and squelch and frequency select. In the short run - and long
run, for that matter - you'd be better off buying a new or good used two
meter rig instead of converting a cell phone.

Many of us out here in the business have carried the 2001 to sites for years. I personally own one and have taken it on aircraft, on snowmobile and hand carried it to the customer's equipment with no trouble at all. Now it must be said there are several flavors of the 2001 and they all weigh a little less as the product got newer. A 2001-A model was the first one to be introduced and is the heaviest. It also was originally equipped with a Magnavox CRT that did not have the life span of the later replacement Telefunken CRT.

The 2001-B has a redesigned power supply which knocked off a couple of pounds but was still fairly much the same monitor. Some of the other internals

were redesigned and made to work a little better.

The 2001-C model was where other options started to be added and I didn't do much with those, but the last time I checked, they were still supported by Motorola Test Equipment Repair.

The 2001-D model was, it could be said, a concept redesign. The handle was placed on the side, several pounds additionally were knocked off the total weight, several features added such as DTMF decode, paging decode, DPL decode and others. The CRT has always been sharp and bright since the Telefunken tube was made standard. I am not going to talk about the trunking or cellular options.

One really important factor about the Motorola product is its RF integrety. The 2001 is really RF tight. That is extremely important when field tuning a duplexer on a customer's site. Most of us don't have the funding to purchase a H/P tracking generator or related equipment so we have to use our trusty service monitors and our skill as technicians (not to mention knowing how to read the manufacturer's directions instead of thinking were smarter than the people who designed the duplexer in the first place) to get the job done. I would take the Motorola line of monitors, hands down, over any IFR product because the units I worked with leak too much. Specifically the 1000A and the 1200 come to mind. The RF output of the 2001 is also right up there at, or just beyond, 1 RF volt. This is important when dealing with cavity transmitter combiners or anything that needs to have some punch applied.

Functionally the 2001 is layed out better. It makes sense. If I need a function, I can find it. The CRT is nice and big so I can see it without needing a microscope.

I really think this club's funding should be put toward a Motorola product. It will not just "suffice", but will be a hard core, heavy duty, long lived piece of equipment that should last for years to come. Of the 2001ABCD units I have worked with, they may be a bit heavy depending upon what you end up with, but they don't break any more than any other test equipment when properly taken care of. As for the weight, I always did say, this hobby was not for wimps.

Message-ID: <4k6ejq$g32@news1.io.org>
Source record: 203225

For anyone who has always wanted a ICOM-781 but couldn't afford it.. read on!

I have a mint (yes, mint) 781 for sale.
I bought it new and have been the only owner.
I don't smoke and the rig is immaculate.

It comes with ALL the manuals including the complete service manual I bought.
This thing has always been pampered. I even keep a soft make-up brush beside
the rig and dust it all the time.

It comes with a replacement CRT unit in case the existing one should ever go.
I planned on keeping this rig for a long time so I bought the replacement CRT
unit just in case. It is still in the ICOM box (yes, it's expensive).

The list goes on....

Please E-mail me only if you are really serious and you can appreciate what
this rig is. If you have dreamed of this rig (as I did), then this is the
deal of a life time.

E-mail me at: iancamp@io.org OR iancamp@interlog.com

Just an additional clarification....
When I said (yes, it's expensive) I meant the CRT unit that comes with the
781... not the offer for sale..

I'm asking about $6500 for it but I'll talk to any serious offers.

Thanks again,

326. Charging sealed lead-acid batteries

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-06 00:00:00 UTC
From: Scott Macmillan <scott@golfmike.demon.co.uk>
Message-ID: <FWIEyBAKCsZxEw00@golfmike.demon.co.uk>
Source record: 203227

Hello, and thanks for reading this.

I just bought a 12V 12Ah sealed lead-acid battery at a rally.

My problem is I dont have the special charger required to charge it.
I know that these batteries require a constant voltage charge of 2.4 to
2.5 volts per cell (14.4 to 15 volts for a 12V battery), and I was
wondering
if I could use my PSU to charge this battery.

My PSU is a Manson EP-925, which has a variable voltage output between
5 and 15 volts, but no control of the current output (25 Amps max).
Is there any need to limit the current output, and if so, how can this
be done.

The only charger unit I have seen for these batteries was in Maplin
Electronics,
but it was only suitable for batteries upto 6Ah, (or so it said in their
catalogue)
and it was 35 quid - more than double the cost of the battery.
Yes, we Scotsmen hate parting with our hard earned cash.

Thanks again for your time.

Source record: 203238

Radios are designed to operate in =all= the bands for which they may be legal in any given region or configuration, so there is only one basic design, and a few components will set the radio up for whatever bandwidth is needed for the application.

Any licensed ham can modify a radio and then use it in the ham bands. However, there are some bands (such as aviation) where the radio must be "type certified" by the FAA, and a modification will void that type certification. With such a radio, it would be illegal to transmit on any frequency other than the ham bands, no matter what other licenses you have... unless you get the radio re-type-certified. (an expensive proposition, as I understand)

>yet?

Dave, take a look at the *radio*, not the schematic. I think you'll
find the parts missing from the board that do 800-950 MHz receive.
That's how Yaesu brought it into compliance with the ECPA. There
aren't any firmware changes that I know about, the radio still
displays the frequencies, it just can't hear them because of missing
parts. If you order the parts and install them on the board, you'll
have a radio that works just like your friend's radio.

>shouldn't try this at home hi hi.

You can say that again, Jim. Not only is there a chance that the
lithium battery will explode, but the heat required to solder tabs
on it can damage it. That's why the tabs are spot welded on in
factory batteries. The very brief pulse of heat used to do the
spot weld won't damage the battery. The relatively long application
of heat needed to solder on the tabs can, and often does, damage
the battery. Just soldering the tabs into the circuit, however,
doesn't expose the battery to much heat, and is relatively safe
to do. The battery can still explode, however, particularly if
you accidentally short it. Be *very* wary of grounded tip soldering
irons in this regard. You might short the battery without realizing
it, and these things can explode like a 12 gauge shotgun shell when
shorted (and I've got a circuit board with a 50 cent piece sized
hole in it to prove it).

>spectrum on the ham 2m band!

Ricochet is a half duplex packet system with a basic baud of 100 kb.
Net throughput is similar to that of a 28.8 kb V34 modem from the
user's perspective (at least with light network loading). It uses
SS, and thus isn't allowed on 2m.

However as a note to Dennis, don't assume that binary FSK modulation
is the only choice on 2m. Remember that a V34 28.8 kb modem operates
in only a 5 kHz bandwidth over the phone, and does that *duplex* to
boot. It does that, of course, by overloading each symbol (baud) with
multiple bits. Or put another way, there are more than 2 possible
symbols and each one represents some combination of bits. The tradeoff
Shannon requires of us in this case is a greater SNR. We must be able
to discriminate one state out of many possible states for each transmitted
symbol (baud).

Occupied bandwidth is a function of baud and modulation technique.
Using M-ary coding, we can maintain a low baud while having a high
bit per second data rate. Given the 20 kHz bandwidth allowed for
digital data on 2m, we should be able to do about 4x the bps of
a V34 modem if certain conditions are met.

We need a very good SNR, with a 40-50 db margin, and we need a
constant frequency response and phase shift on the channel. A
good SNR isn't too difficult for us to achieve, but frequency
and phase consistency is very difficult with the varying brands
of radios and modems used in amateur radio, except for the special

case of dedicated non-contending duplex links. Then the modems can train, as they do on the phone line, to deal with the frequency response and phase response of that particular pair over that particular path.

We don't usually operate that way, so we use much more bandwidth inefficient techniques to avoid the need for training and consistent frequency and phase response between disparate pieces of radio equipment operating from multiple locations over varying quality paths in a contending environment. But we don't *have* to operate that way. We *could* engineer switched radio networks that behave similarly to the telephone system, and thus take advantage of the bandwidth conserving techniques used by phone modems.

I've got one, the hetrodyne notcher and narrow filters work Ok, the
noise reduction doesn't. For $50, it's Ok, but it doesn't compare to
some of the better units. It does have nice loud audio output though.

>more than enough for the local repeaters, right (Waldorf/LaPlata, MD area)?
>Any suggestions are welcome.

The HTX-202 is about the best 2m HT on the market. Its intermod
resistance is better than anything else out there thanks to very
tight front end filtering (which limits it strictly to ham band
only, it is not a wide coverage scanner). With a 12 volt battery,
it'll make over 5 watts. It is big and clunky by today's standards,
but it takes room to fit in those good filters.

The HTX-212 isn't so special. It's not a bad radio, but it isn't
a great radio either. There are a number of 2m mobile rigs that
are its equal or better. None of those better radios have a name
that begins with 'K' however. Alinco, Icom, Standard, and Yaesu
all make better radios (at least some models are better, even
that crowd has been known to turn out a squalling lemon).

My normal advice is that a HT is a specialist tool, for foot mobile
operation. For a rig to move back and forth between car and home,
get a real mobile rig and a quick release mounting bracket. Something
with good filters and 45 watts of power. You'll be happier, and those
who have to listen to you will be happier too.

>conversations?

I guess if you expect to find everytime you call CQ the person answering is going to be somebody you want to talk to more than hello, how's the weather and what gear you running. It isn't that way in life. I have very few "friends" but many acquaintances. It took many meetings and conversations to find those few friends. Same holds true on the radio. It is unrealistic to expect to hold a technical conversation with everybody. OTOH, I can't recall any extended operating time that I haven't heard people talking about something I would enjoy joining in on. Geeze, in the last 3 months I have run into 2 people that fly RC airplanes, another hobby of mine. Wasn't easy but no harder than finding the buddies I fly with now.

Bottom line, ham radio is what YOU make out of it.

Hi Gary,

You need toi be a little more careful with your remarks. The error in the half wave line is yours, and you have made it before. Let me explain why.

In article <1996Apr5.224816.15395@ke4zv.atl.ga.us>, gary@ke4zv.atl.ga.us (Gary Coffman) writes:

>A 1/2-wave wire is naturally resonant, and will have a voltage *maxima*
>at its ends, regardless of whether it is excited in the middle or on
>one of its ends.

Totally untrue Gary. If the far end of a half wave is grounded, or connected to a low impedance, the near end will also be a low impedance. Remember Gary, the half wave **repeats** what is going on at the far end. A 1/4 wl inverts it!

If the far end is connected to a low impedance current source, which a dipole excited with RF can be, minimum common mode current will appear in the middle of the half wave feedline. Maximum current will appear in the snack, just where you don't want it.

This is exactly why coaxial sleeve baluns are 1/4 wl long, and not a 1/2 wl !

>In fact, if it is excited at one of its ends, the
>impedance presented will be thousands of ohms.

Not if the other end is grounded!

>That's why the fellow
>at Dayton was right, and Tom is wrong. Because the end of the coax
>outer looks like thousands of ohms when it is a 1/2-wave *physical*
>length. The currents at the antenna will divide unequally with most
>of the current flowing into the low impedance of the 1/4-wave half
>of the dipole, and very little trying to turn the corner and flow
>into the high impedance presented by the coax outer end.

You made the same error as the "expert" at Dayton, Gary.

>Tom's mistake is trying to use transmission line theory on what is *not*
>at this point functioning as a transmission line. It is, instead, an
>unintended end fed 1/2-wave antenna. Now while it is true that the
>ends of such an antenna are voltage maxima, that's because the ends
>are very high impedances, and thus not much current will "turn the
>corner" to excite this "antenna", so there won't be much high voltage
>down at the shack end. OTOH, a 1/4-wave will be a low feed impedance
>at the antenna, thus lots of current will divert down toward the shack,

>and will express itself as a high voltage at the high impedance of the
>other end. (And the other end *will* be a high impedance because the
>current can't penetrate the coax shield or the transmitter case to
>"close the loop" with the driving source. Whether the transmitter case
>is connected to Earth or not is largely irrelevant as well.)

Gary's mistake is forgetting a half wave repeats what ever happens at the
far end.
I'll accept an I'm sorry>;-)

In article <1996Apr5.225848.15483@ke4zv.atl.ga.us>, gary@ke4zv.atl.ga.us (Gary Coffman) writes:

>That's assuming the currents are flowing to "ground", Jack. But
>that's not what they do.

Of course they do Gary. When dealing with common mode currents, the line must be treated like a single conductor.

The path is from the voltage source (in this case the antenna) at the to another low impedance point (in this case the rigs chassis and everything it connects to). The concept is commonly misunderstood, but here's how it works in the case of a dipole.
Assume a transmitter with a coaxial output connection to a dipole antenna. Each half of the antenna is excited by the differential voltage at the end of the coax. Since each half of the antenna has a low self impedance (it is a 1/4 wave with an open far end)m at the feedline terminals, a finite voltage will appears from each terminal to any electrical mass not charged with exactly the same voltage.

You can prove this by touching the dipole at each side of the center insulator. No matter where you stand, you'll get a burn! The rapidly changing voltage tries to charge and discharge your body, and current flows in your fingers.

The feedline is no exception, and since the center conductor of the line is not connected to the rest of the world the same way as the shield, current will flow on the feeder. Since the current has no equal and opposite current to force it to the center of the cable, it appears on the shield.

If the cable presents a low common mode impedance to the antenna, considerable current will flow. If the common mode impedance is zero ohms, the shield half of the antenna will have NO current at all. All of the current that used to excite that half of the antenna will simply turn and flow back down the outside of the line. The theoretical maximum common mode current is equal to the current in the half of the antenna attached to the center conductor. Each side of the antenna has around 30 ohms of impedance, so with 100 watts of excitation the current will be 1.82 amperes with a common mode impedance of zero ohms. The feedpoint will see a 30 ohm load.
With a common mode impedance of 30 ohms at the feedpoint, the center conductor side of the antenna will have 1.49 amperes of current, the common mode current will be .745 amperes, and the side of the antenna connected to the sheild wil, have .745 amperes of current at the feedpoint. The overall impedance at the feedpoint will be 45 ohms in this

case.

This is why changing the length of the feedline changes the SWR when a balun isn't used at the feedpoint of a coax fed dipole, and the source of the myth "moving the meter causes a false SWR reading"!

If the distance to the rig (or any other ground) is 1/2 wl electrical for common mode signals, a low common mode impedance appears at the antenna terminals.
If a "ground" or low RF impedance is placed on the feedline 1/4 wl from the antenna feedpoint, the antenna sees a high common mode impedance and balance remains pretty good even without a balun.

Kirchoff is completely satisfied, as he must be, at every point in each of these systems.

The Raymond Sarrio Company's Ham Radio WWW site is proud to announce a FREE Ham Radio classified advertising page at http://www.csz.com/sarrio.html.

This new classified section will allow Hams to search for equipement with the help of a search engine--no need to scroll through 100's of listing before you find that special piece of gear. Plus, when you find the gear your interested in, each listing comes with point-and-click e-mail access, direct to the Ham that listed the item.

For those Hams with gear to sell, take note! It is absolutely FREE to list your equipment within Ham Classifieds, and there will be no posting time delays. Your posting will go on-line, in our classified search engine, immediately. All you need do is fill out a simple forms page, and upon its (point-and-click) submission, your "For Sale" advertisement is on-line within 1 hour. I will be purging the classified listing initially about once every month, but that timeline will shorten as our classified numbers go up. Give it a try, and let me know how you like it. 73's Ray

From: sba3020@InfoNET.st-johns.nf.ca
Message-ID: <4k52uj$t6b@coranto.ucs.mun.ca>
Source record: 203310

Not happy with your Icom R1 or just want a base scanner.

I will trade you a Realistic PRO-2022 200 channel scanner that covers the full 800 MHz band including cellular. Same style as the PRO-2005 or PRO-2006

This is one of the scanners that scan cellular in the proper 30 kHz steps and not 12.5 kHz steps.

200 channels divided into 10 groups of 20 channels and 10 monitor memories

Scanner has programmable priority channel, direct search and limit search.

I believe the CE-232 and HB-232 computer interface can be connected to this scanner.

Radio comes with original manual and box.

>inside a Faraday box called a transmitter.

Gary, this has nothing to do with Kirchoff's law. Once the RF exits the coax at the antenna, it will be attracted to *any* conductor that has a lower EMF than itself. It doesn't matter whether that conductor is the antenna, the shield, the B- of the transmitter, or twelve bronzed monkeys holding hands and singing Nowhere Man. Anything the RF can reach that will conduct, dissipate or radiate is fair game.

>The RF currents on the outside of that box can't get in, can't close
>the loop, and therefore that model fails.

The only model that fails is the one you've described, because it doesn't exist. Not only is the inner chassis of the transmitter not the primary target of the current, it isn't even sealed. Take the key jack for example. One conductor is usually connected to the external chassis by the frame of the jack. The other conductor typically has a bypass capacitor from the tip of the jack to the inner chassis. So what happens when you close the key? Zappo! The outer chassis is connected to the inner chassis through the key and the bypass capacitor. This is also why the key contacts often spark when there's RF on the chassis of the transmitter.

The point is Gary, the concentrically-shielded RF source you're envisioning doesn't exist relative to currents flowing on the outer cabinet. Even if you don't agree with anything else, you should at least abandon this concept.

------------------------------
I have the Radio Shack DSP model 21 I think, I think it works fine for CW.
I can pick out some sigs buried in the novice portion of 40m at night with it
and it is very easy to set up and VERY easy to use. Mostly plug and play.
I have turned it on SSB on several bands and it seems to work ok but not great.
But for $50 (or less) not a bad buy. Also it's compact size sure helps in the
shack. If you want one for SSB primarily, you probably need to look at the
Timewave line. Several friends have them and swear by them. But my Rat Shack
unit works great on my Galaxy V. It is a 12v unit. Hope this helps.

Kevin,

It sounds like they have improved the Motorola 2001 since my first experience with it. When I worked for a utility company two-way shop we had one of the first 2001 units. That damn thing spent more time in Motorola's repair shop than it did in our shop. Most of the problems were display related.

I left the company before the problems were resolved so I don't know what they ended up doing with the unit. I hope Motorola gave them a good deal to upgrade the unit.

Which Model are you trying to use? I have one that has a dynamic mic
element, and all I did was to bypass the electronics, and feed the radio,
Kenwood TS-940, direct. The output is lower than most dynamic
elements, but it works good.

372. Coax Shield Current (Was Re: MFJ Artificial Ground)

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-07 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <4k91tp$gjv@crash.microserve.net>
Source record: 203172
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.antenna

Our news server crashed today so I'm not sure my first copy of this went out. Likewise, Gary's article still hasn't appeared here, so I'm commenting on the basis of the text Tom quoted.

w8jitom@aol.com (W8JI Tom) wrote:
>(Gary Coffman) writes:

>>Tom's mistake is trying to use transmission line theory on what is
>>*not* at this point functioning as a transmission line.

The concept of 1/4 and 1/2 wave lines applies equally well to single conductors. This is evidenced by the use of 1/4 wave single-conductor decoupling stubs in microwave circuitry.

>>It is, instead, an unintended end fed 1/2-wave antenna. Now while it
>>is true that the ends of such an antenna are voltage maxima, that's
>>because the ends are very high impedances, and thus not much current
>>will "turn the corner" to excite this "antenna", so there won't be
>>much high voltage down at the shack end.

This paragraph entirely contradicts itself in trying to prove that a 1/2 wave conductor will isolate antenna currents from the transmitter. First it states that because the 1/2 wave shield simulates a 1/2 wave end-fed antenna, the voltage and impedance on both ends will be high. Then it says that because little current will flow, one end will actually be low.

>>OTOH, a 1/4-wave will be a low feed impedance at the antenna, thus
>>lots of current will divert down toward the shack, and will express
>>itself as a high voltage at the high impedance of the other end.

Another contradiction; this paragraph says the same thing about the 1/4 wave shield that the previous paragraph said about the 1/2 wave - that one end will have a higher impedance than the other. This time it's true, but the rest of the explanation is incorrect.

Yes, there is a low feedpoint impedance at the antenna, but it's created by the 1/2 wave dipole, not the shield. The 1/4 wave shield looks like a high impedance due to reflections from the other end, therefore current does not flow toward the shack as claimed.

>>(And the other end *will* be a high impedance because the current
>>can't penetrate the coax shield or the transmitter case to "close
>>the loop" with the driving source.

This is also incorrect. The RF voltage at the antenna is a free agent that is attracted to *all* conductive objects with a lower potential. That includes any object connected to earth or to the B- of the transmitter, as well as any object large enough to convert the current into radiated energy. The latter is the "electrical mass" that Tom often refers to.

Let's analyze the transmitter in this regard. If it was totally isolated from earth, the outer chassis would "float" at some RF potential due to the connection between the chassis and the outer shield of the coax. This would be true regardless of shield length, because in practice even the input impedance of a 1/4 wave shield (at the antenna) won't be infinitely high and some current will flow.

However, the trasnmitter is not isolated from earth. It is coupled to earth by means of AC lines and other equipment. Even if this coupling is very loose, it is sufficient to pull the chassis to near-ground potential due to the isolation provided by the 1/4 wave shield.

As a side note, earth is likely to be more effective at this than even a direct connection to the inside of the transmitter. Unlike earth, the effectiveness of B- as a return path for common-mode current is determined in part by the relative phase between current leaving the transmitter and current arriving at B- by way of the shield.

It's also my belief that the outer chassis of a transmitter is not well-isolated from internal grounds as previously claimed, and that phase and amplitude differences are the real reason the shield current cannot be cancelled by merely returning to B-. At the very least, this lack of isolation appears to be confirmed by the fact that RF on the outer chassis will often create internal equipment malfunctions.

>>Whether the transmitter case is connected to Earth or not is largely
>>irrelevant as well.)

This statement can only be accepted if one believes that RF voltage is not attracted to earth.

73,
Jack WB3U

Nate,
Maybe your not trying hard enough. Maybe if you made more contacts and
talked about YOUR interests someone will say "Hey, I'm into that too!". Maybe
a post on the radio newsgroups asking if anyone wants to talk about (Insert
subject here) on a sked you'd find someone. Maybe a person your talking to
knows someone with the same interests. I'm into astronomy and even though I'm
only a tech plus at the moment I'm hopeing to find someone on 10 meters to
talk astronomy with eventually. I'm going to upgrade to, I'm shooting for
General next. Maybe you just have to work harder at finding your idea of
interesting conversation.

>be done.
>
Scott, the current will not be a problem....with a constant voltage charger 9such as a PS) you will be ok IF you set the voltage to 13.8V max...not 14+...If memory serves, the recommended charge is 2.33V per cell in a float condition....

In our -48V battery systems at telecom sites, we use -54V while floating the cells across the system....The charge current rises sharply on initial charge but then levels to normal operating current (after the batteries have taken the charge). Make sure your voltage does not change under a major load by a significant amount...Best way to set the voltage is with NO load including the battery,,,then after setting the supply voltage, attach the battery and let it charge...Your voltage will return to what the preset was when the battery is fully charged..

I've been an amateur radio operator for about 1 1/2 years now, and been surfing this news group for about a year. I have recieved quite a lot of useful information while browsing. The only thing I find that is most distressing is the slams/spams of what appears to be new operators who ask what appearto be "STUPID" questions.

I have seen a lot of literature which talks about an elmer to help new hams out. Why isn't this true on this news group as well? Come on floks, be a good will ambassador here as well! Help those who don't know. I ahve spent 15 years in both the Army as well as the Navy, and as an instructor in both, I have started each class with the statement-"The only stupid question is the one you did not ask, if you don't know, ask and find out, any questions?"

IMHO. R. Haig KB0PVU.

> I just fixed mine for $1.39.

This reminds me of a very odd defect that was experienced by several models of Sony AM/FM stereo receivers back in the 70's.

Sony had plated the tuning capacitors with some type of alloy that would cause microscopically-thin strands of crystalline metal to "grow" between the plates after a few years of use. The strands were totally invisible to the naked eye, but would short the capacitor and cause the front end to go dead. The cure was to either brush between the plates with a very soft brush, or blow out the cap with compressed air.

I was in the service business the first time I ran into this, and it was exceedingly difficult to convince the customer that we had repaired his stereo with air. I finally had to show him the service bulletin from Sony. ;)

Our news server crashed today so I'm not sure my first copy of this went out. Likewise, Gary's article still hasn't appeared here, so I'm commenting on the basis of the text Tom quoted.

w8jitom@aol.com (W8JI Tom) wrote:
>(Gary Coffman) writes:

>>Tom's mistake is trying to use transmission line theory on what is
>>*not* at this point functioning as a transmission line.

The concept of 1/4 and 1/2 wave lines applies equally well to single conductors. This is evidenced by the use of 1/4 wave single-conductor decoupling stubs in microwave circuitry.

>>It is, instead, an unintended end fed 1/2-wave antenna. Now while it
>>is true that the ends of such an antenna are voltage maxima, that's
>>because the ends are very high impedances, and thus not much current
>>will "turn the corner" to excite this "antenna", so there won't be
>>much high voltage down at the shack end.

This paragraph entirely contradicts itself in trying to prove that a 1/2 wave conductor will isolate antenna currents from the transmitter. First it states that because the 1/2 wave shield simulates a 1/2 wave end-fed antenna, the voltage and impedance on both ends will be high. Then it says that because little current will flow, one end will actually be low.

>>OTOH, a 1/4-wave will be a low feed impedance at the antenna, thus
>>lots of current will divert down toward the shack, and will express
>>itself as a high voltage at the high impedance of the other end.

Another contradiction; this paragraph says the same thing about the 1/4 wave shield that the previous paragraph said about the 1/2 wave - that one end will have a higher impedance than the other. This time it's true, but the rest of the explanation is incorrect.

Yes, there is a low feedpoint impedance at the antenna, but it's created by the 1/2 wave dipole, not the shield. The 1/4 wave shield looks like a high impedance due to reflections from the other end, therefore current does not flow toward the shack as claimed.

>>(And the other end *will* be a high impedance because the current
>>can't penetrate the coax shield or the transmitter case to "close
>>the loop" with the driving source.

This is also incorrect. The RF voltage at the antenna is a free agent that is attracted to *all* conductive objects with a lower potential. That includes any object connected to earth or to the B- of the transmitter, as well as any object large enough to convert the current into radiated energy. The latter is the "electrical mass" that Tom often refers to.

Let's analyze the transmitter in this regard. If it was totally isolated from earth, the outer chassis would "float" at some RF potential due to the connection between the chassis and the outer shield of the coax. This would be true regardless of shield length, because in practice even the input impedance of a 1/4 wave shield (at the antenna) won't be infinitely high and some current will flow.

However, the trasnmitter is not isolated from earth. It is coupled to earth by means of AC lines and other equipment. Even if this coupling is very loose, it is sufficient to pull the chassis to near-ground potential due to the isolation provided by the 1/4 wave shield.

As a side note, earth is likely to be more effective at this than even a direct connection to the inside of the transmitter. Unlike earth, the effectiveness of B- as a return path for common-mode current is determined in part by the relative phase between current leaving the transmitter and current arriving at B- by way of the shield.

It's also my belief that the outer chassis of a transmitter is not well-isolated from internal grounds as previously claimed, and that phase and amplitude differences are the real reason the shield current cannot be cancelled by merely returning to B-. At the very least, this lack of isolation appears to be confirmed by the fact that RF on the outer chassis will often create internal equipment malfunctions.

>>Whether the transmitter case is connected to Earth or not is largely
>>irrelevant as well.)

This statement can only be accepted if one believes that RF voltage is not attracted to earth.

387. INFO WANTED ON COLLINS 637K-series (AS-2259/GR) HF Antennas

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-07 00:00:00 UTC
From: mc@shore.net
Message-ID: <4ka0vv$6ii@northshore.shore.net>
Source record: 203187
Cross-posted to: rec.radio.amateur.equipment,rec.radio.swap

Hello to All Boatanchor Buddies:

I have a Collins 637K-1 HF Manpack antenna set (Mil number is AS-2259/GR). This was used primarily with the PRC-47 and was made to be easily carried and set up in the field. It covers 3-30MHz and were sold by Fair Radio Sales in their 1994 catalog.

The manual lists a couple of variants on the 637K-series, such as:

637K-2 which is the addition of "a 200 Watt-PEP, manually tuned antenna coupler with an RF sensor and tuning meter". This was used with other HF radios not having sufficient tuning range for coupling to the antenna such as the KWM-2.

637K-4 which is the addition of a 30 Watt PEP, manually tuned antenna coupler with an FR sensor and tuning meter for use with radios such as the AN/PRC-74, AN/PRC-64 and the AN/GRC-109.

I am interesting in knowing more about these two antenna couplers such as model numbers and hopefully find someone who has either ot both of these available for sale or trade. With all the expertise here I am hoping to find out more about these two couplers.

Can anyone help?

73,

Michael Crestohl, KH6KD/W1

Sorry if this is off topic, but this is the best group I could find on my server for this question. A guy I know gave me a Technics SA-R177 stereo reciever, he said it was broken. His description of the problem was "The sound gradually went, and then it was dead." All the controls and such work fine, but I haven't had any luck getting any sound out of it. I checked all the connections I could find, and they all seemed fine. If anyone has a schematic or knows of any common probs with the SA-R177 reciever, I would appreciate it if you could email me (my news server sucks, and I don't want to burden anyone with an off topic thread.) My email address is friedo@supernova.net.

Thanks a lot for any help you can offer :)

Date: 1996-04-07 00:00:00 UTC
From: sdrumm@albert.nuc.umr.edu
Message-ID: <4k8o6p$ngo@hptemp1.cc.umr.edu>
Source record: 203194

I just recently received my no-code Tech license, and the time has now come to purchase a radio. I'm looking for a 2m HT that is small and rugged enough to be carried when backpacking, hunting, hiking, etc.

Members of the local club recommended the ICOM IC-T22A for $245, and I was wondering if anyone has had positive/negative experiences with this particular model and/or company.

Also, what features should I be looking for in a handheld unit in the $250-$350 price range? I'm a little vague on what DTMF, coded squelch, and tone squelch features actually *do*, so any help in that area would be appreciated.

Thanx for the assist!

>Thank you for any help you might be able to offer.
>
>73, Gary

Gary, I did draw up an interface between the Tr7625/7600 and an ACC rptr controller using the FC-1 interface (BCD outputs)...

The 7600/7625 do not use DIRECT BCD control...actually, the 144-146 and 146-148 Mhz bands are repeated in the BCD dtring...an extra input changes the LO xtal to offset the PLL sothe BCD inputs are used on both segments! (IE: say 200 is the divisor for 144,000...it is ALSO the same at 146 but the XTAL is changed in the rig!)...

I dont think I have the copy of the manual anymore...but if I run across the drawing i did, I'll let you know IF it can be of any help..

(the manual was borrowed from a friend of mine...he MAY still have it... I'll check and see)

Does anybody know of any interface circuits for adapting a telephone style Plantronics Starset headset to radio use. I have noticed something like that but I can not remember where I saw it. If anyone can help please e-mail me with information.

Thanks,
Rich Elliott KC7CDK
relliott@cyberhighway.net

Our news server crashed today so I'm not sure my first copy of this went out. Likewise, Gary's article still hasn't appeared here, so I'm commenting on the basis of the text Tom quoted.

w8jitom@aol.com (W8JI Tom) wrote:
>(Gary Coffman) writes:

>>Tom's mistake is trying to use transmission line theory on what is
>>*not* at this point functioning as a transmission line.

The concept of 1/4 and 1/2 wave lines applies equally well to single conductors. This is evidenced by the use of 1/4 wave single-conductor decoupling stubs in microwave circuitry.

>>It is, instead, an unintended end fed 1/2-wave antenna. Now while it
>>is true that the ends of such an antenna are voltage maxima, that's
>>because the ends are very high impedances, and thus not much current
>>will "turn the corner" to excite this "antenna", so there won't be
>>much high voltage down at the shack end.

This paragraph entirely contradicts itself in trying to prove that a 1/2 wave conductor will isolate antenna currents from the transmitter. First it states that because the 1/2 wave shield simulates a 1/2 wave end-fed antenna, the voltage and impedance on both ends will be high. Then it says that because little current will flow, one end will actually be low.

>>OTOH, a 1/4-wave will be a low feed impedance at the antenna, thus
>>lots of current will divert down toward the shack, and will express
>>itself as a high voltage at the high impedance of the other end.

Another contradiction; this paragraph says the same thing about the 1/4 wave shield that the previous paragraph said about the 1/2 wave - that one end will have a higher impedance than the other. This time it's true, but the rest of the explanation is incorrect.

Yes, there is a low feedpoint impedance at the antenna, but it's created by the 1/2 wave dipole, not the shield. The 1/4 wave shield looks like a high impedance due to reflections from the other end, therefore current does not flow toward the shack as claimed.

>>(And the other end *will* be a high impedance because the current
>>can't penetrate the coax shield or the transmitter case to "close
>>the loop" with the driving source.

This is also incorrect. The RF voltage at the antenna is a free agent that is attracted to *all* conductive objects with a lower potential. That includes any object connected to earth or to the B- of the transmitter, as well as any object large enough to convert the current into radiated energy. The latter is the "electrical mass" that Tom often refers to.

Let's analyze the transmitter in this regard. If it was totally isolated from earth, the outer chassis would "float" at some RF potential due to the connection between the chassis and the outer shield of the coax. This would be true regardless of shield length, because in practice even the input impedance of a 1/4 wave shield (at the antenna) won't be infinitely high and some current will flow.

However, the trasnmitter is not isolated from earth. It is coupled to earth by means of AC lines and other equipment. Even if this coupling is very loose, it is sufficient to pull the chassis to near-ground potential due to the isolation provided by the 1/4 wave shield.

As a side note, earth is likely to be more effective at this than even a direct connection to the inside of the transmitter. Unlike earth, the effectiveness of B- as a return path for common-mode current is determined in part by the relative phase between current leaving the transmitter and current arriving at B- by way of the shield.

It's also my belief that the outer chassis of a transmitter is not well-isolated from internal grounds as previously claimed, and that phase and amplitude differences are the real reason the shield current cannot be cancelled by merely returning to B-. At the very least, this lack of isolation appears to be confirmed by the fact that RF on the outer chassis will often create internal equipment malfunctions.

>>Whether the transmitter case is connected to Earth or not is largely
>>irrelevant as well.)

This statement can only be accepted if one believes that RF voltage is not attracted to earth.

You guys have totally ignored the issue of type acceptance. While not required for CAP, type acceptance is required for most land-mobile radio operation in the public and private services. Using a modified ham radio in these areas is illegal.

Source record: 203261

So, who else has seen the brochure about the 5900?

It's remotely controllable by DTMF tones -- I certainly didn't expect
that!
The good old 5718 has no remote control feature. Hey, I wonder if the
9600bps packet interface is any better in the 5900; With the 5718, I had
to
put an amplifier circuit inline between the MFJ-9600 modem and the 5718's
data port, because the 5718 wanted 5 volts peak-to-peak.

And, I wonder how well the Double Balanced Mixer and Tracking Front-End
really do in preventing intermod. Sounds interesting, because intermod
does get through my 5718 receiver at home, especially on the 70cm band.

Then there's the Yaesu FT-50R which is described at
http://www.yaesu.com/whatnew.html . Interesting, but I wonder what
happened
to the ALL NEW: Cellular phone capability. Maybe it's just not
documented:-)

>Voltage is the work function between two points, it is not attracted
>to anything in particular because there is nothing to attract, it's a
>*potential*, not a substance.

Gary, no offense, but this couldn't be more ambiguous. Voltage is
attracted to all unlike voltages. Is that what you mean by "anything
in particular"? If so, it contradicts your earlier claim that shield
currents radiate when they are unable to "close the loop" inside the
transmitter (which you say is their only attraction).

Also, unless you believe that a charge on an object is imaginary,
voltage is indeed a substance. It is the "essential nature" of
the objects under discussion. We can feel it, we can see its effects,
and we can measure it.

>The potential difference between two points can cause a current to
>flow, dependent on the impedance value between those two points,
>but the potential of Earth is *undefined* in absolute terms, and
>different for any two points measured on its surface.

Absolute terms aren't important to an analysis of shield currents.
It's the *relative* differences between between earth, the
transmitter, the RF at the antenna, etc. that we're concerned with.

>We can't say absolutely that RF current will be attracted to Earth;
>with the proper phasing it could well be *repulsed* by Earth at a
>particular point and time instead.

If a wire is connected between the output of a transmitter and ground,
current will flow on the wire to earth. Varying the phase of the
signal won't change that.

>Or the two points could share the same (high) potential when viewed
>from a third point. Etc. It is too simplistic to assume that Earth is
>a magnet for electricity, a sponge willing to sop up any amount of
>current with no concern for work functions, phase, etc.

First, imaginary third points aren't relevant to this discussion. Second, the earth *is* a magnet for the RF we generate and it will soak up more than even Tom's amplifiers can produce. ;)

>We can't view voltages, currents, or impedances in isolation.

We also can't view them from the Crab Nebula and expect to understand the relationship between the components of the system.

>They're all part of a whole which also includes distance and
>time.

Is this a Zen thing? ;)

>That's why I asked Tom what units he uses to measure "electrical
>mass". The kilogram is a unit of mass, but I don't think he was
>referring to mass at all, but to something else.

The concept of electrical mass is valid regardless of Tom's lack of specific definition. Tom could probably refer to the earth in terms of its total charge capacity, its effective surface area at various frequencies, its absorptive characteristics, etc. However, considering that the resultant numbers would be so extreme in comparison to the components we're discussing, I don't think the specifics are particularly useful.

We don't need to know how much RF the transmitter would have to feed to earth in order to modulate the entire planet. All we need to know is that earth provides a potential that is different than the RF voltage we generate and that there will be an attraction between the two.

>We can only call an Earth connection low impedance if we can define
>the current loop and the other point to which our voltage measurement
>is referenced. If we can't close that loop, or supply that other
>point, there's nothing we can say about an impedance.

If the output of an ungrounded transmitter is coupled to a short wire and the other end of that wire is connected to earth, current will flow to earth. That current will *not* return to the transmitter.

If we measure the current in the wire with an RF ammeter and we also measure the output power of the transmitter (at an internal point with a low differential impedance), we can determine the impedance of the connection to earth without knowing either the voltage at the output of the transmitter or the relative or absolute voltage on earth.

The concept that the circuit must be visibly "completed" in order for RF current to flow is false, as is the claim that we must be able to define a "loop" in order to analyze the circuit.

gary@ke4zv.atl.ga.us (Gary Coffman) wrote:

>That's assuming the currents are flowing to "ground", Jack. But
>that's not what they do. The current is trying to "close the
>loop" back to the source, Kirchhoff's law, and the source is
>inside a Faraday box called a transmitter.

Gary, this has nothing to do with Kirchoff's law. Once the RF exits the coax at the antenna, it will be attracted to *any* conductor that has a lower EMF than itself. It doesn't matter whether that conductor is the antenna, the shield, the B- of the transmitter, or twelve bronzed monkeys holding hands and singing Nowhere Man. Anything the RF can reach that will conduct, dissipate or radiate is fair game.

>The RF currents on the outside of that box can't get in, can't close
>the loop, and therefore that model fails.

The only model that fails is the one you've described, because it doesn't exist. Not only is the inner chassis of the transmitter not the primary target of the current, it isn't even sealed. Take the key jack for example. One conductor is usually connected to the external chassis by the frame of the jack. The other conductor typically has a bypass capacitor from the tip of the jack to the inner chassis. So what happens when you close the key? Zappo! The outer chassis is connected to the inner chassis through the key and the bypass capacitor. This is also why the key contacts often spark when there's RF on the chassis of the transmitter.

The point is Gary, the concentrically-shielded RF source you're envisioning doesn't exist relative to currents flowing on the outer cabinet. Even if you don't agree with anything else, you should at least abandon this concept.

Kirk,

No such luck on the Logic Boards with the 5 pin jack. The pinouts
are:

1. External Speaker - (a.k.a. Chassis Ground).
2. External Emergency Switch Input
3. External Alarm (Horns or Lights)
4. External Speaker + (Audio out to Ext Spkr AND Int Spkr)
5. Ignition Control (If Internal Jumper F801 is Cut)

Note: F801 is the common designation for all Logic Boards that have
the 5 Pin Option Jack.

From: mc@shore.net
Message-ID: <4kat31$239@northshore.shore.net>
Source record: 203017
Cross-posted to: rec.radio.swap,rec.radio.amateur.equipment

Hello to All Boatanchor Buddies:

I have a Collins 637K-1 HF Manpack antenna set (Mil number is AS-2259/GR). This was used primarily with the PRC-47 and was made to be easily carried and set up in the field. It covers 3-30MHz and were sold by Fair Radio Sales in their 1994 catalog.

The manual lists a couple of variants on the 637K-series, such as:

637K-2 which is the addition of "a 200 Watt-PEP, manually tuned antenna coupler with an RF sensor and tuning meter". This was used with other HF radios not having sufficient tuning range for coupling to the antenna such as the KWM-2.

637K-4 which is the addition of a 30 Watt PEP, manually tuned antenna coupler with an FR sensor and tuning meter for use with radios such as the AN/PRC-74, AN/PRC-64 and the AN/GRC-109.

I am interested in knowing more about these two antenna couplers such as model numbers and hopefully find someone who has either ot both of these available for sale or trade. With all the expertise here I am hoping to find out more about these two couplers.

Can anyone help?

73,

Michael Crestohl, KH6KD/W1

gary@ke4zv.atl.ga.us (Gary Coffman) wrote:

>I'm also fascinated with your fondness for the peculiar properties
>you assign to "ground" and "electrical mass".

I've been thinking that the crux of this argument might be the perceived impedance of the transmitter chassis. I finally decided to look up the subject of antenna current in the ARRL Antenna Handbook.

The discussion in the Handbook is centered on the use of balanced feeders, but a subsequent paragraph states that the discussion applies equally well to coax. I think the text is sufficient to resolve much of our disagreement (unless we choose not to believe it). ;)

Here's what I found:

1. The first scenario presented in the discussion tends to agree with Gary's claim regarding use of a 1/2 wave long shield. It states that the total length of the line plus one side of the 1/2 wave antenna should *not* be an integral multiple of 1/2 wave. In other words, the feedline should *not* be an odd multiple of 1/4 wave.

However, the condition to which this is applied is when the line is connected to a coupling circuit that is not grounded, either directly or through a capacitance of more than a few picofarads.

2. The second scenario agrees with the claim by Tom and myself that a 1/4 wave shield should be used. It states that the feedline plus one side of the antenna should be equal to multiples of 1/2 wave. In other words, the feedline should be an odd multiple of 1/4 wave.

The condition this applies to is when "the coupling apparatus is grounded at the transmitter." The text goes on to say that "in the average station, it is not possible to get a connection to real ground without having a lead that is an appreciable fraction of a wavelength long" but "if the trasnmitter has fairly large capacitance to ground, a system of this length will be effectively detuned for the fundamental and all even harmonics when grounded to the transmitter at the coupling apparatus."

The latter agrees closely with what I've been saying about the ability of the loose coupling to ground being able to pull the "residual" voltage to near-ground potential, so long as a 1/4 wave line is used.

To sum this up, when coax is used, the system does *not* present the extremely high impedance to ground that might otherwise require

the use of a 1/2 wave line. If coax is in use and the station is operated in the usual manner, a 1/4 wave line will detune the system for antenna currents.

My perfect CW station just consists of gear I can afford. With all the bells
and whistles on today's gear, the perfect station becomes a quest of personal
preference and the ability of your wallet to support those choices.

I really enjoy the thrill of DX ing with my Drake 2NT running 35 watts on
crystal control to a trap vertical. I also enjoy working QRP with my HW 8.
Of course my TS830s does a really great job also. It just really depends what
my mood is as to which station I get on the air with.

Good luck in your quest for the perfect station

In article <4k9to3$rqr@cu.comp-unltd.com> saremington@imt.net (Scott Remington) writes:
>Could someone please explain what 'type acceptance' is and why it's so
>important (to the FCC)?

Ok, I'll try. Type Acceptance is a specific set of design criteria and performance criteria that a radio has to meet, in a FCC lab test, before the FCC will allow it to be used in certain radio services (most radio services other than amateur). There are a number of performance criteria having to do with spectral purity, modulation acceptance limits, and the like that it has to meet under a number of specified environmental conditions so that a *non-technical operator* can use it with reasonable assurance that it won't cause an interference hazard to other users, particularly life safety service users, operating on other channels.

In addition, the radio must have other design factors so that the user can not change the radio's operating frequency to one where he is not licensed to operate. This latter is a fairly recent addition to the Type Acceptance criteria for land mobile radios, though it has always been true for CB radios. Older land mobile radios could be user programmed to other frequencies. Unthinking operators did that, and caused problems, so now it is forbidden for Type Accepted radios to be frequency programmable by the user onto frequencies for which they do not hold a license. Typically the radio shop that sells the radio will program it using a special interface and software to only the channels the buyer is licensed to use.

This requirement is a pain in the ass to amateurs when and if such equipment falls into their hands via the surplus channel, of course, since it makes it difficult to make the radio frequency agile in the amateur bands. That's the price we pay for idiots operating out of band. The FCC is beginning to get ticked about amateur radios being modified for out of band operation too, and has started to put pressure on the importers to make the radios harder to modify. This is also a PITA for legitimate users who need wider coverage for MARS/CAP or for driving a transverter.

The whole point of Type Acceptance is to try to make it difficult for the operator to operate the radio illegally, and to make sure that a non-technical user won't inadvertently cause interference to users on other channels through spurious radiation or due to excessive modulation or other funky behavior caused when he does something dumb, like operate into a bad antenna.

If too many amateur radios start showing up on the channels of services where they are not approved, we're likely to see a repeat of the HF external amplifier rule which imposed Type Acceptance on those amplifiers because they were being so widely

abused on the CB band, IE we may find that our VHF/UHF radios
will be required to be Type Accepted, showing only channel numbers
with no way for the user to change the frequencies stored in those
channels.

Amateurs are assumed to be technically skilled (they've been tested)
and are assumed to know the regulations (they've been tested) and
it is assumed that they will abide by the rules (they're supposed
to self-police) so Type Acceptance hasn't been imposed on amateurs.
But if abuse becomes rampant, as it did with external power amplifiers,
then Type Acceptance might be imposed, and that would be a horrible
black eye to the amateur service, not to mention that it would drive
the price of amateur radios through the roof. So don't use amateur
radios where Type Accepted radios are required.

>
> Any info would be helpful. Thanks!

Your aquaintance is a joker. This rig is affectionately
known as a boatanchor. It is a very large, very heavy
all vacuum tube plate modulated AM transmitter. It is
not a transceiver as is the norm today, so you also need
a separate receiver to use with it. An old Hallicrafters
or National would be a good match.

These old rigs can sound good on AM, but they're somewhat
dirty with respect to TVI and your neighbors won't be very
happy with you. Also some of the tubes are getting harder
to find and are becoming expensive. Since there isn't a
lot of AM activity on the amateur bands these days, the
phone contacts you will make will be limited to other
nostalga buffs who like to play with this old equipment.
It's over 40 years old. The transmitter will also do CW
of course, so you can use it that way. However, frequency
stability isn't up to modern standards and that can lead
to frustration.

One of these old rigs would make a fine restoration project
if that's what you like to do, but I would definitely not
recomend it as a beginner rig.

> and thus transmission line theory does not apply.

Wave reflection theory will apply.

>2) The outside of the coax is acting as a halfwave resonant
structure, IE antenna, and antenna theory must apply.

Antenna theory based on unterminated lines will not apply. The 1/2
wave shield is not unterminated.

>3) The standing wave on a halfwave antenna forces the ends to be
> voltage maxima.

This is true of both the antenna and the 1/2 wave shield.

>4) Ergo, the ends of a halfwave antenna are high impedance points.

This statement is true, but because of the error in (2), it does not
apply to the 1/2 wave shield.

>5) And finally, a high impedance load driven by a low impedance
> source won't accept much current. Therefore use of a halfwave
> coax feeder will limit the amount of RF current conducted down
> to the shack end of the coax along the coax's outer surface.

The first sentence is true, but no valid basis for the conclusion has
been presented.

>Now tell me where any of that is wrong, and we can proceed from
>there.

In a nutshell, you're mixing absolute and relative terms. You've used
"low" when the correct term is "less", and "high" when the correct
term is "greater". This has led to incorrect conclusions regarding
both the 1/2 wave and 1/4 wave shield lengths.

You're also applying theory based on unterminated conductors to a
shield that is terminated by a finite degree of coupling to earth at
the transmitter.

Source record: 203030

David,
I also have the Alinco610. I don't see how it is possible
to get the 800 Mhz. to work, as this takes a separate module
that is not installed in the radio. The control head does
contain the red and blue wires as listed in various mods., but
in this case hardware is also missing.

Hi Gary,
In article <1996Apr8.004633.25164@ke4zv.atl.ga.us>, gary@ke4zv.atl.ga.us (Gary Coffman) writes:
>
>You persist in treating this wire as a transmission line when that
>is not how it is operating.

Of course it is! Even an antenna can be analyzed as a transmission line, there are whole articles and sections of textbooks that treat antennas this way. An antenna is really an opened up transmission line. Electromagnetic Waves and Radiating Systems (Jordan-Balmain, Prentice Hall EE series, second edition page 388 amoung many).

Broadcast towers (even dipoles and other antennas) are commonly treated as transmission lines with a single conductor impedance (Zo). If a single wire **can't** act like a transmisssion line, then how do long wires function?

The truth is, the conductor is both a radiator AND a transmission line.

>I would ask you, what is the impedance
>of "ground", and between what two terminals are you measuring it?

The system is impossible to quantize, but in approximation the large conductive mass of the station ground is a reasonably low impedance. If not, we wouldn't be able to end feed wires at all without a radial system. With changing voltage, any conductive mass has impedance.

>And why would that matter anyway? Transmission line currents must
>form a closed path, and this path is not closed.

Are you actually saying that I can't excite a single conductor with RF, and have current and voltage appear for many wavelengths along that conductor unless there is a "return path" from the far end?

>It is not behaving
>as a transmission line. It is behaving as an excited resonant 1/2-wave
>antenna structure. *The point where the excitation is applied does
>not change the standing wave pattern on the radiator.* It must have
>voltage maxima at its ends.

Let me see if I understand this statement. Are you saying, if I ground the far end of a half wave antenna, the current maximum STILL occurs in the middle instead of the end?

>[snip]
>>Gary's mistake is forgetting a half wave repeats what ever happens at

the
>>far end.
>>I'll accept an I'm sorry>;-)
>
>If you can demonstrate that this current flow on the coax outer
>is a closed path transmission line current, I'll say I'm sorry,
>or at least grumpily acknowledge I'm wrong. I don't believe that
>it is, so I don't agree with your conclusions. And yes, I know there
>are such things as single wire transmission lines, but that doesn't
>apply here since both ends of the line are not operating against
>"ground", and thus don't form a closed path for the transmission
>line currents to follow.

Are you saying I can't feed a Windom with a single wire transmision line?
After all, both ends aren't grounded.

>1) The outside of the coax is not acting as a transmission line,
> and thus transmission line theory does not apply.

Antenna's act like transmission lines, and imperfect transmission lines
act like antennas. If what you say is true, connecting the far end of a
half wave long conductor to a low impedance (for example it could be the
near end of a 1/4 wave open ended wire, or a ground rod, or a radial
system, or a large conductive mass), will not change the current
distribution in that half wave conductor. We know that isn't true.

If I terminate the ends of a half wave center fed antenna in any low
impedance electrical mass (and even if there is no "return path"), your
"theory" dictates the center impedance would remain a current maxima. We
know that isn't true.

If what you're saying is true, I can put up a half wave dipole and
ANYTHING I do at the dipole ends won't change the current distribution or
feedpoint impedance!

I have a BTI (Brad Thompson Industries) 2KW linear for sale. For those of you that may not be familiar with BTI - this amp looks a lot like a Henry 2K. It is meant to sit on the floor and is on casters. It uses one 3-1000Z as the final output tube. This unit covers 10-80 meters and will run 2KW all day long. It can be configured to run 120 or 240 volts and has a built in thermostatically controlled cooling blower. Make me an offer.

What you might have seen is a Motorola 800 Mhz ESMR trunked radio that is proved by Nextel. It is digital with 1.5 to 2 watts and does full duplex interconnect and 2 way radio. In northern California, Nextel system covers from Redding to the north to Fresno in the south and the Bay Area. Not bad for wide coverage.

I got to use one for a week, and it has different audio quality than FM, but it was consistent no matter what part of the network you came in on.

I am getting interested deeply in 6m allmode and EME.
I have a YAESU FT-990dc w/35 amp external supply in perfect
condition that I bought last March 95. In order for me to
get the allmode equiptment I will have to sacrifice the
990 and supply... cost 1800.00 plus after shipping and will
sell for 1400.00 firm. This setup allows the Nice HF you
may have wanted and a 35 amp supply to run it and your whole
shack.

Also for sale is my LK500zc Amp Supply 2kw amp... Legal Limit
plus.... it is in beautiful condition and well cared for.
I installed 2 brand new 3-500zg tubes (graphites) for the heck
because it had the same tubes in it from the beginning.
I did not see an appreciable power gain so the old tubes were
in great shape (sold the old ones). I figure the graphites
will never have to be replaced... will sell for 1300.00 firm.

All prices are firm and you pay for shipping.....

73.... Cal, N4UTN.....

Is anyone familiar with the batch 17 radios? It's inbetween where they
switched layouts for the resistor pads and none of the current mods that
I have seen seem to work for me. Does anyone have any suggestions?
I'd love to have a general purpose receiver.

Cheers,
David N0YMV

I want to thank all who responded to my inquiry regarding the Ten Tec Omni VI.

For the information of all.. I did not recerive a single negative response, aside from one minor complaint that the radio did not include a general coverage receiver. (Ham bands only)

The great consensus was that this rig is the equal of, or exceeds the finest rigs out there, with regards to it's ability to "hear". This opinion applied mostly to CW and the digital modes, but most thought that it did a fine job on SSB and other "voice" modes also..

A couple of repondees also felt strongly about the fact that the Ten Tec is an American made transceiver.

Again, thanks to everyone... Bill KN6FJ

446. The Transmitter Chassis (Was MFJ Artificial Ground)

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-08 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <4kcftv$iuo@crash.microserve.net>
Source record: 203049
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.antenna

The discussion regarding artificial grounds and coax shield currents has raised a related issue that I think is widely misunderstood.

First, it was stated in the other discussion that feedline currents radiate because they are unable to enter the transmitter and return to their source. I have disputed this because there are many openings and pathways into the typical transmitter for current flowing on the outer chassis. If the current is attracted to the inner chassis, and it appears that it is, it can find a way in. The evidence of this is that RF in the shack often causes the internal workings of the transmitter to malfunction. In addition, removing the cabinet of the transmitter will typically have little or no effect, good or bad, on the RF in the shack.

It has also been stated that because the outer chassis of the transmitter is at a high impedance point, use of a 1/2 wavelength transmission line (coax shield) is appropriate for discouraging common mode current from travelling from the antenna to the transmitter. The high impedance seen at both ends of the cable supposedly will not allow significant current flow.

In turn, I have disputed this, for two reasons. The first has to do with the ability of external currents to enter the transmitter as mentioned above. These currents do enter the transmitter, therefore the outer cabinet is not an isolated point in free space with a high impedance. The second reason for my disagreement with this statement is that in the typical Amateur installation, there is considerable capacitance between the transmitter and earth. This brings me to the issue at hand.

For purposes of this discussion, assume we have a 100 watt HF transmitter and that the cabinet has been removed. Also assume that the transmitter has an internal power supply and that the supply is fed with a 2-wire 120 VAC line cord. Other than two feedthrough capacitors and perhaps a pair of small series RF chokes, there is nothing between the line cord and the primary of the power transformer. A 50 ohm shielded dummy load is attached to the output of the transmitter.

The transmitter just described is an RF generator that is matched to its load. One output terminal is the center pin of the SO-239 jack at the rear panel. The other output terminal is the flange around that pin. If the transmitter is keyed, the center pin of the jack will be "hot" with RF. However, the flange and the chassis of the transmitter to which it is bolted will not. If a low-capacitance oscilloscope is

grounded through a good RF earth ground at the frequency of operation, it will be discovored that the voltage on the center pin is close to the calculated value (E = sq root (P*R)) and that the voltage everywhere on the chassis is a very low value. This can be further verified by the fact that touching the center pin will cause a burn, but touching the chassis will not.

Now, considering that the AC voltage at the two output terminals of an isolated generator will be equal amplitude and opposite phase, how can the preceding be true? Shouldn't the flange of the connector (and thus the chassis of the transmitter) have the same RF voltage as the center pin? The answer is yes, it should, and if we perform the same test with a solid-state mono *audio* amplifier, we would find that the AF voltages on the chassis and on the "positive" output terminal are in fact nearly identical.

The reason for the difference between these two models is that capacitance between the transmitter's chassis and ground unbalances the transmitter's output, causing the chassis to assume the reference potential supplied by ground. This capacitance is small, in fact too small to have an appreciable effect at audio frequencies. However, its capacitive reactance (impedance) decreases as the frequency rises, and at RF it provides a current path sufficient to reference the voltage on the chassis to ground.

In the example given, capacitance will exist between the primary and secondary of the power transformer, as well as between the inner and outer connections to the bypass capacitors on the AC line. There will also be capacitance between the AC wiring and ground, and if this wiring is the correct length, it may even act as a counterpoise or as a low impedance path to the electrical ground of the AC mains.

To explain further, if the transmitter were operated in free space with a self-contained power supply, there would be no tendancy for it to favor either the chassis or the center conductor of the output terminal in terms of the voltage that appears at those points. There is nothing inherent to the transmitter itself that causes the chassis to be "cold" and the output terminal to be "hot". Therefore, even the slightest external influence will be sufficient to pull one or the other toward the voltage potential that exists on that external influence. In our case, the influence is earth.

Lastly, the preceding discusses voltage but not current. We know that one connection to the output connector is the center pin and that the other connection is the chassis itself. Further, because this is an RF generator, the current in the center pin must be equal and opposite to the current entering the flange from the chassis. If that's the case, why doesn't the chassis radiate? Well, in fact it does, but because the chassis is only a small fraction of a wavelength, the current established by the 50 ohm load is insufficient to create appreciable radiation from the chassis.

As a side note, this should not be taken to mean that a small antenna cannot be made to radiate efficiently. If a wire the size of the chassis were actually matched to the output of the transmitter, it would radiate profusely. However, in the process of matching it to the transmitter, the current flowing through the wire would increase many times over the current that is flowing on the chassis of the transmitter.

In summary, even if the transmitter is not intentionally grounded, the voltage on the chassis of the transmitter is held at near-ground potential by virtue of capacitance between the chassis and earth. The chassis may also be referenced to earth by external cabling (including the AC line) and other equipment to which the transmitter is attached. This establishes the chassis as a lower impedance point than would otherwise be the case, and it plays an important role in determining the shield length necessary to minimize common mode currents.

73,
Jack WB3U

Funny you should mention about the BC stations. I had been wondering for several months why according to my MFJ-249 my 160/80/40 antenna has a much better SWR at night than at day, and why the daytime reading "danced around", until a ham friend pointed out that AM stations switch to their low power at sundown.

In article <Dp8rM0.7y9@twisto.eng.hou.compaq.com>,
Monty Wilson <mwilson@bangate.compaq.com> wrote:

>really knew his stuff. The forum I attended was on coax and other
>feedlines, and one subject he covered was this business of using an
>electrical half-wavelength feedline. He explained the several reasons

Hi Monty, an electrical half-wavelength feedline (neglecting losses)
will reproduce the antenna impedance. If the antenna impedance is
50 ohms and the feedline is 50 ohms, then the feedline length
doesn't matter. If the antenna impedance is not 50 ohms, you
probably don't want to reproduce it. Rather, you probably want
to transform it as close to 50 ohms as possible by some other
length of feedline.

Maybe he was suggesting a halfwavelength feedline when the antenna
impedance is 50 ohms and one is feeding it with ladder-line. Then
it would make sense. Trying to find a coax length that is a multiple
of halfwavelengths for all HF bands doesn't make sense since the
antenna is probably non-resonant. Again if you have multiple
dipoles such that the antenna impedance is 50 ohms on all bands
(dream on) then the coax length doesn't matter since the SWR is
a perfect 1:1.

On top of all that, halfwavelengths are a poor choice because
of the impedance presented to common mode currents. But it does
make sense when feeding a 50 ohm antenna with ladder-line.

BASIC PACKAGE:

* R-4C Receiver (serial # 16320)
* T-4XC Transmitter (serial # 20489)
* MS-4 Speaker
* AC-4 Power Supply

INCLUDED EQUIPMENT & ACCESSORIES:

* Crystals for WARC, WWV, etc.

* CW filters -- 250 Hz + 500 Hz

* Owner's manuals --
Excellent condition, no underlining, no torn
pages, and no coffee stains.

* Original connecting cables in mint condition.

DETAILS:

* All units are in excellent, near-mint condition.

* R-4C recently aligned by Drake at their
Franklin, Ohio facility.

* NO dents!

* NO stains!

* Absolutely original condition. NO mods!

* Know defects:

o Missing cover for the accessory crystal sockets at
the rear of the R-4C.

o Finals a bit weak on the upper freqs.

Can someone point to the specific text of the CFRs that prohibit the end-user from programming land mobile gear?

I'm a bit confused on this... CURRENT production Bendix-King and Icom land mobile rigs (including stuff that's come out in the last year) is keyboard programmable via a "password" or by shorting some pins in the mic connector.. And now Motorola, the king of non user-programmable radios has introduced the JT-1000 series, which is programmable via the front panel.

What gives?

Someone said that the manditory non user programmability never made the law books, but was only recommended. Maybe the manufacturers figured out a way around it with keyboard passwords or temporary jumpers?

463. Mods For Alinco 610???

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-08 00:00:00 UTC
From: David Mclean <dmclean@dfw.net>
Message-ID: <316980B8.77F0@dfw.net>
Source record: 203196

Hell all:

I have the alinco 610 mods. I think that mods open the 800mhz up on
the radio. Has any one tried the mods and goten the 800mhz part to work!
Thanks for the help! If you need the mods for the radio send me e-mail and I
will send them to you.

>Remember Gary, the half wave **repeats** what is going on at the far end.
>A 1/4 wl inverts it!

You persist in treating this wire as a transmission line when that
is not how it is operating. I would ask you, what is the impedance
of "ground", and between what two terminals are you measuring it?
And why would that matter anyway? Transmission line currents must
form a closed path, and this path is not closed. It is not behaving
as a transmission line. It is behaving as an excited resonant 1/2-wave
antenna structure. *The point where the excitation is applied does
not change the standing wave pattern on the radiator.* It must have
voltage maxima at its ends.

[snip]
>>In fact, if it is excited at one of its ends, the
>>impedance presented will be thousands of ohms.
>
>Not if the other end is grounded!

Again, what impedance is "ground", and between what two points
are you measuring it? I continue to sense an unwarranted mystical
belief about "ground" in your postings. It is merely a large somewhat
conductive sheet, and can have any potential at any given point
depending on where you place the other measuring probe.

[snip]
>Gary's mistake is forgetting a half wave repeats what ever happens at the
>far end.
>I'll accept an I'm sorry>;-)

If you can demonstrate that this current flow on the coax outer
is a closed path transmission line current, I'll say I'm sorry,
or at least grumpily acknowledge I'm wrong. I don't believe that
it is, so I don't agree with your conclusions. And yes, I know there
are such things as single wire transmission lines, but that doesn't
apply here since both ends of the line are not operating against
"ground", and thus don't form a closed path for the transmission
line currents to follow.

Let me try to summarize my case so that we can focus on the exact
point of disagreement.

1) The outside of the coax is not acting as a transmission line,
and thus transmission line theory does not apply.

2) The outside of the coax is acting as a halfwave resonant structure,
IE antenna, and antenna theory must apply.

3) The standing wave on a halfwave antenna forces the ends to be
voltage maxima.

4) Ergo, the ends of a halfwave antenna are high impedance points.

5) And finally, a high impedance load driven by a low impedance
source won't accept much current. Therefore use of a halfwave
coax feeder will limit the amount of RF current conducted down
to the shack end of the coax along the coax's outer surface.

Now tell me where any of that is wrong, and we can proceed from
there. I suspect that you will dispute 1, but if you do, you must
close the current loop and demonstrate how that occurs, no mysticism
about "ground" allowed. :-)

I'm not just trying to get an argument going here. I really am
curious how you think the current loop can close through the
Faraday shield of the coax outer and transmitter case. I'm also
fascinated with your fondness for the peculiar properties you
assign to "ground" and "electrical mass". Is the latter measured
in pounds? :-) (That may seem like a joke, but I really want to
know, what units do you assign to "electrical mass"?)

[I wrote]
>>>Whether the transmitter case is connected to Earth or not is largely
>>>irrelevant as well.)
>
>This statement can only be accepted if one believes that RF voltage
>is not attracted to earth.

Jack, I'm going to reply to the rest of your post later, but I want
to address this now. Voltage is the work function between two points,
it is not attracted to anything in particular because there is nothing
to attract, it's a *potential*, not a substance. The potential difference
between two points can cause a current to flow, dependent on the impedance
value between those two points, but the potential of Earth is *undefined*
in absolute terms, and different for any two points measured on its surface.

We can pick a point and call it zero, because all potential difference
measurements are relative, but we can't *assume* it will be some
particular value with respect to some other point. It takes two
separated points to have a potential difference, and that difference
can vary by time, location, phase, or magnitude. We can't say absolutely
that RF current will be attracted to Earth; with the proper phasing it
could well be *repulsed* by Earth at a particular point and time instead.
Or the two points could share the same (high) potential when viewed from
a third point. Etc. It is too simplistic to assume that Earth is a
magnet for electricity, a sponge willing to sop up any amount of
current with no concern for work functions, phase, etc.

We can't view voltages, currents, or impedances in isolation.
They're all part of a whole which also includes distance and
time. That's why I asked Tom what units he uses to measure
"electrical mass". The kilogram is a unit of mass, but I don't
think he was referring to mass at all, but to something else.
If we knew the units he was using, we might infer the nature
of what he thinks he is describing. You suggest he is talking
about something with the units of length, that he's referring
to something large enough to radiate significantly at the
frequency of interest. But that's only a part of the story
isn't it? That radiation depends critically on other factors
too, such as current flows and geometry, lack or presence of
balancing flows, standing waves formed by resonances, etc.

In short, an Earth connection, a ground, does not automatically
imply a low impedance. That's because one of the factors establishing

impedance is potential, and that varies between any two given points.
We can only call an Earth connection low impedance if we can define
the current loop and the other point to which our voltage measurement
is referenced. If we can't close that loop, or supply that other point,
there's nothing we can say about an impedance.

Gary

Making mods is not illegal, using the modified equipment for services
for which the modified equipment is neither type accepted nor licensed
is. Since no amateur rigs (excluding HF external amplifiers) require
type acceptance, it is not illegal to use a modified commercial radio
in the amateur service. The vice is not, however, versa.

Cross-posted to: rec.radio.amateur.equipment,alt.america.online,alt.anarchism,alt.art.colleges,alt.models

Give this note to your friends to make big bucks.
Hello! I've got some awesome news that I think you need to take two minutes to read if you have ever thought "How could I make some serious cash in a hurry???" , or been in serious debt, ready to do almost anything to get the money needed to pay off those bill collectors. So grab a snack, a warm cup of coffee, or a glass of your favorite beverage, get comfortable and listen to this interesting, exciting find!

I was scanning thru a NEWSGROUP and saw an article stating to GET CASH FAST!! I thought..."Here on the Internet?? Well, I'll just have to see what schemes could possibly be on the internet." The article described a way to MAIL A ONE DOLLAR BILL TO ONLY FIVE PEOPLE AND MAKE $50, 0000 IN CASH WITHIN 4 WEEKS! Well, the more I thought about it, the more I became very curious. Why? Because of the way it worked AND BECAUSE IT WOULD ONLY COST ME FIVE DOLLARS (AND FIVE STAMPS), THAT'S ALL I EVER PAY....EVER!!

Ok, so the $50,000 in cash was maybe an tough amount to reach, but it was possible. I knew that I could at least get a return of $1,000 or so. So I did it!! As per the instructions in the article, I mailed out ('snail mail' for you e-mail fanatics) a single dollar bill to each of the five people on the list that was contained in the article. I included a small note, with the dollar, that stated "Please Add Me To Your List." I then removed the first position name of the five names listed and moved everyone up one position, and I put my name in position five of the list. This is how the money starts rolling in! I then took this revised article now with my name on the list and REPOSTED IT ON AS MANY NEWSGROUPS AND LOCAL BULLETIN BOARD MESSAGE AREAS THAT I KNEW. I then waited to watch the money come in...prepared to maybe receive about $1000 to $1500 in cash or so.... But what a welcome surprise when those envelopes kept coming in!!! I knew what they were as soon as I saw the return addresses from people all over the world -Most from the U.S., but some from Canada, even some from Australia! I tell you, THAT WAS EXCITING!! So how much did I get in total return? $1000? $5000? Not even!!! I received a total of $23,343!!! I couldn't believe it!!

I now have a brand new black Acura Integra to speak for, due to this!! Now after almost 8 months, I am ready to do it again!!! So maybe it was possible to get $50,000 in cash, I don't know, but IT COMPLETELY DEPENDS ON YOU, THE INDIVIDUAL! You must follow through and repost this article everywhere you can think of! The more postings you achieve will determine how much cash will arrive in your

very own mailbox!! It's just too easy to pass up!!!

Let's review the reasons why you should do this: The only cost factors are for the five stamps, the 5 envelopes and the 5 one dollar bills that you send out to the listed names by snail mail (US Postal Service Mail). Then just simply repost the article (WITH YOUR NAME ADDED) to all the newsgroups and local BBS's you can. Then sit back and, (ironically), enjoy walking (you can run if you like! :o) down your driveway to your mailbox and scoop up your rewards!! We all have five dollars to put into such an easy effortless investment with SPECTACULAR REALISTIC RETURNS OF $15,000 to $25,000 in about 3-5 weeks! So HOLD OFF ON THOSE LOTTERY NUMBERS FOR TODAY,
EAT AT HOME TONIGHT INSTEAD OF TAKEOUT FROM McDONALDS AND INVEST FIVE

DOLLARS IN THIS AMAZING MONEY MAKING SYSTEM NOW!!! YOU CAN'T LOSE!!

So how do you do it exactly, you ask? I have carefully provided the most detailed, yet straightforward instructions on how to easily get this underway and get your cash on its way. SO, ARE YOU READY TO MAKE SOME CASH!!!?? HERE WE GO!!!

*** THE LIST OF NAMES IS AT THE END OF THIS ARTICLE. ***

OK, Read this carefully. Get a printout of this information, if you like, so you can easily refer to it as often as needed.

INSTRUCTIONS:

1. Take a sheet of paper and write on it the following: "Please add my name to your list". This creates a service out of this money making system and thus making it completely legal. You are not just randomly sending a dollar to someone, you are paying one dollar for a legitimate service. Make sure you include your name and address. I assure you that, again, this is completely legal! For a neat little twist, also write what slot their name was in: "You were in slot 3", Just to add a little fun! This is all about having fun and making money at the same time!

2. Now fold this sheet of paper around a dollar bill ,(no checks or money orders), and put them into an envelope and send it on its way to the five people listed. The folding of the paper around the bill will insure its arrival to its recipient. THIS STEP IS IMPORTANT!!

3. Now listen carefully, here's where you get YOUR MONEY COMING TO YOUR MAILBOX. Look at the list of five people; remove the first name from position one and move everyone on the list up slot one on the list. Position 2 name will now move to the position 1 slot , position 3 will now become position 2, 4 will be 3, 5 will be 4. Now put your name, address, zipcode AND COUNTRY in position 5, the bottom position on the list.

4. Now upload this updated file to as many newsgroups and local bulletin boards' message areas & file section as possible. Give a

catchy description of the file so it gets noticed!! Such as: "NEED FAST CASH?, HERE IT IS!" or "NEED CASH TO PAY OFF YOUR DEBTS??", etc. And the more uploads, the more money you will make, and of course, the more money the others on the list will make too. LET'S ALL TAKE CARE OF EACH OTHER BY BEING HONEST AND BY PUTTING FORTH 120 PERCENT INTO THIS PROFITABLE & AMAZING SYSTEM!!! You'll reap the benefits, believe me!!! Set a goal for the number of total uploads you'll post, such as 15-20 postings or more! Always have a goal in mind!!!
If you can UUE encode the file when uploading, that will make it easier for the people to receive it and have it downloaded to their hard drive. That way they get a copy of the article right on their computer without hassles of viewing and then saving the article from the File menu. Don't alter the file type, leave it as an MS-DOS Text file. The best test is to be able to view this file using Microsoft's Notepad for Windows 3.x or WordPad for Windows '95. If the margins look right without making the screen slide left or right when at the ends of the sentences, you're in business!

5. If you need help uploading, simply ask the sysop of the BBS, or "POST" a message on a newsgroup asking how to post a file, tell them who your Internet provider is and PEOPLE WILL ALWAYS BE GLAD TO HELP. I would try to describe how to do it but there are simply too many internet software packages with slightly different yet relatively simple ways to post or upload a file. Just ask for help or look in the help section for 'posting'. I do know that for GNN, you simply select 'POST' then enter a catchy description under the subject box, choose 'ATTACH', selecting 'UUE' and NOT 'TXT', then
choose 'Browse' to go look for the file. Find your text file CASH.TXT and click on it and choose 'OK'. Place a one line statement in the main body section of the message post screen. Something like "Download this to read how to get cash arriving in your mailbox with no paybacks!" or whatever. Just make sure it represents its true feasibility, NOT something like..."Get one million dollars flooding in your mailbox in two days!" You'll never get ANY responses!

6. And this is the step I like. JUST SIT BACK AND ENJOY LIFE BECAUSE

CASH IS ON ITS THE WAY!! Expect to see a little money start to trickle in around 2 weeks, but AT ABOUT WEEKS 3 & 4, THE MONEY STORM WILL HIT YOUR MAILBOX!! All you have to do is take it out of the mailbox and try not to scream too loud (outside anyway) when you realize YOU HIT THE BIG TIME AT LAST!!

7. So go PAY OFF YOUR BILLS AND DEBTS and then get that something special you always wanted or buy that special person in your life (or the one you want in your life) a gift they'll never forget. ENJOY LIFE!

8. Now when you get low on this money supply, simply re-activate this file again; Reposting it in the old places where you originally posted and possibly some new places you now know of. Don't ever lose this file, always keep a copy at your reach for when you ever need

cash. THIS IS AN INCREDIBLE TOOL THAT YOU CAN ALWAYS RE-USE TIME AND
TIME AGAIN WHEN CASH IS NEEDED!

9. (This step added by Margaret Morris). Hello, This is exciting
isn't it?! While I'm on the list, just add a note saying "Please
include extra money tips" with your name & E-MAIL address, and I will
(FOR FREE) send you some neat methods to increase the money you will
receive with this plan.
Why?... Why not? I'm not selfish...I like helping out others.
E-mail just makes it a touch easier and cheaper, too! After I drop
off the list, I can no longer offer you this advice, obviously, but
maybe someone else who gets my tips will offer and simply replace my
name on this step number 9. Good luck and give this plan your all, it
will definitely pay off!
Like Mike said, HAVE FUN WITH IT!!!

469. Problem with Icom 751A CW carrier drift

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-08 00:00:00 UTC
From: Mat Eshpeter <mat@clearnet.com>
Message-ID: <4ka0fn$3fr@dub-news-svc-1.compuserve.com>
Source record: 203202

I have noticed that the carrier transmitted by
my Icom 751A in CW mode will drift just after
I have begun sending a "block" or group of
characters.

The drifting occurs about 1 second into the
transmission. The "drift" is actually a
very small frequency shift that is just large
enough to be detectable as a difference
in pitch (when monitored on a second rig that I
was using to listen to my CW signal).

Once the drift is complete (takes a few hundred
milliseconds, and is continuous in nature, not a
discrete jump), the frequency does not change
again, until I stop sending characters for a
second or two. I was transmitting with both
minimum and maximum power, and there were no
chirps or keyclicks. I was using a Bencher paddle
and the internal keyer.

Any 751A owners out there have this problem, and know of
a fix ? You can try email, but it is up and down like
a yo-yo. Please post to this newsgroup.

Thanks
Mat

Quite so. Unhappily, the FCC has been using the fact that an amateur radio
was modified as evidence that it was improperly used outside of the amateur
bands where equipment should have been type accepted. Thus actually using
the radio to unlawfully transmit is not required to generate trouble for
yourself. Very nasty attitude actually...

Then came the term VELOCITY FACTOR. Where velocity factor, "v", is
expressed as a percentage by :

v = 100c' / c

where c' represents the speed of propogation in a particular
substance, and c is the speed of light in a perfect vacuum. Both c'
and c must be specified in the same units. -Amateur Radio Encyclopedia

Martin Lynch Ltd, a UK dealer has 781 for sale, I think he's had it for a long time. I think he want 2000ukp for it, this would work out to $3200?

I don't think Icom will be importing any more 781's as the internal CRT does not meet with local EMC regulations, I have was informed.

Sexy radio though....excellent for data modes and for using with a transverter...or so I'm told.

`lo all. Well I hope I'm posting this in the right area, but I have a big problem, and I'd be very grateful if anyone can help me with it... it goes like this:

My mom frequently enjoys listening to a provincial radio station (CBC). Unfortunately whenever my computer (Pentium-90) is on, it interferes with the station and there is a high pitched noise in the background of the station (the loudness varies from day to day). If anyone has any suggestiongs please send email to brendan@direct.ca

An acquaintance of mine (without net access) recently purchased a
Link 1907 ED.2A
at a local hamfest. It's an *old* tube-driven VFH monster, apparantly rigged
w/ Civil Air Patrol duplex crystals.

Of course, there was no documentation at all with it (it looks to be an
antique :o), so he's interested in anything anybody might know or have
stashed away: specs, anecdotes, etc.

Please respond by e-mail and I'll repost.
(I just don't have the bandwidth to keep up with this newsgroup.)
Thanks in advance.

>
>I too, like Motorola monitors...I have a 2002B and a R-2456A...
One word of caution on the 2000 series...although they are really good monitors, they have stopped making parts for them and no longer support anything older than a "D" series...As time goes by, they will stop supporting them also, simply due to their age...There is an occasional bargain though, I recently rebuilt three 2000 series monitors, replacing the CRT's, several boards, power supplies and completely overhauling them to practically new...I sold one for $3K and the other for $2,800. (missing handle) I kept the nicest one for myself. You can probably find a nice R-2400 series, or maybe even an older R-2600 or 7550 for around $5K. Try Leasametrics Inc. in Dallas...they rent them out for a year or two and them sell them at (frequently) very good prices. They calibrate them before they leave and sell them complete with warranty. I have bought stuff from them before and been very pleased...A used R-2400 (monitor, spectrum analyzer etc.) should run around $5k, depending on age. A R-2600 will probably run a bit more...If you can find a R-7550, they sell new for about $8K...used price for one two or three years old would probably be in your price range..Regards...M.T. From: kd4geu@aol.com
Message-ID: <4kd6as$k5q@newsbf02.news.aol.com>
Source record: 203073

Hello:
I have an older Yaesu FT-530 that's about 3 years old
and its one that only took the solder pad 13 mod. My question
is that it will only transmit up to about 456.000mHz but at
that freq it flutters at keyup, its quite about 454.000mHz.

Does anyone have any suggestions to get the unit to
transmit up to 470.000mHz. I did the same mod on a friend's
530 and his will transmit up around 470.000 to my jealously.

I have permission to use a 460 business band repeater,
and would like to be able to do so with the 530.

I think the 530 is a excellent radio and hate to see them
discontinue it. Any help with my mod will be appreciated.

Thanks for reading this!

Get a 850 ! There does not seem to be much difference to the 450, but there
are some small yet important advantages. The most important to me is the 850's
"slope tune" which works by adjusting the second and third oscillator and
allows for blanking out unwanted signals that are close to the station you're
listening to. This feature is very helpful against heavy qrm, both on ssb and cw.

Bob:

A lot depends on its condition bo�th electrically and cosmetically. If
there are any extra holes in the metal, or irreversible modifications or
its in generally rough condition then it's worth little. On the other
hand if its pristine and original its worth a lot more.

Something is only worth as much as a seller is willing to accept in order
to sell it. But a clean original Ranger is worth some decent bux!

I like to work on and use older SS (Solid State) gear.
I'm primarily interested in ICIR, Alda, Atlas, Cubic, Astro (cubic), Stoner,
and other early solid state HF transceivers including military and
any National, Hammerlund or military solid state receivers.

I'm particularly interested in dead and or problem radios (priced accordingly).
I'll also trade repairs for radios (have a good bench)

I've got ISDN hardware and other datacom hardware to trade plus
some ham gear.

Boatanchors available for trade...
BC669 and R32.

Also have a Melco (Hygain) CB converted to 10m FM, a Sinclair 'MicroMatic'
(advertised as the worlds smallest transistor radio when new, 1.5" x 1" x .5")

and a Decibel products remote antenna monitoring system with 7 directional
couplers (all unused) to trade.

Jack:

I believe that Gary has a point in that the circuit back to the transmitter must be (visibly) completed. To me this means that the current that leaves the transmitter in the center lead of the coax must return to the transmitter in some manner. Generally, this is throught the shield of the coax. If it did not return, then the negative charge of the electrons leaving the radio would leave a positive charge on the case of the radio.

Mat,
It sounds like you might have a problem with the regulation in your power supply. The voltage may be dropping when you load it down by transmitting.

> Any info would be helpful. Thanks!

A Viking II was a ham radio transmitter manufactured in the mid to late 1950's. It had two 6146 tubes in the final and two 807's as modulators. The rig was noteable for it's continous tuning capability from 1.8 to 30 mHz, utilizing a roller inductor in the final amplifier. The transmitter needs an external VFO to operate or you may plug in a crystal in the crystal socket for fixed, drift free, operation. The output power is just over 100 watts if the tubes are good. The chassis is copper plated and weighs about 75 pounds. You can find one at a hamfest for around $75 to $100 if you're lucky, as it is becoming a collectors item.

Of course you'll need to buy a companion receiver to compliment your transmitter.

>73,
>Jack WB3U

Hi Jack:

Not in my mind. The fields exist between the line and the ground plane(s) and cannot exist without them. Therefore, the "second" conductor(s) must be there.

Imagine this: A length of coax has its outer conductor slit lengthwise. If the slit is infinitely narrow, the line behaves pretty much as before. Now we open the gap slightly. There is a slight change in impedance and a little bit of leakage (radiation). There is also a tiny bit of dispersion (different frequencies propagate at different velocities). We continue to open the gap and all of the above continue to occur. Finally, we have the shield bent completely open to a flat conductor. The line continues to operate, but now we have a round wire above a groundplane. Is the center conductor a "single" wire line? No it isn't. If we now squish the dielectric and wire flat, we have microstrip. Has anything really changed? No again.

> 73--Phil (KB1GO)
You are definitely correct... I used to use the HG-10 VFO when I ran the set
with a Heath SB300 receiver. However, my external power supply (SB300) went
south to a new ham to get him started on the air. So I don't have an external
supply to run the vfo. I use it with the HW 16 novice rig at times. However I
keep getting a chirpy signal on 15 mtrs. Seem the OO's out there like to mail
me notification cards on it but they don't seem to want to tell me about it on
the air. For all the OO's out there... Yes I do have a regulated B+ line so
you can quit putting that cure on the notices :-}

Maybe this was a bad analogy. What if the 1/4 wave line is formed
into a half turn loop (like a hairpin) that's perpindicular to the
ground plane?

I don't want to get stuck on this if it isn't relevant to the other
discussion; I'll just say it isn't the same thing and let it go. ;)

From: srwhite@ibm.net
Message-ID: <4ke3op$40pc@news-s01.ny.us.ibm.net>
Source record: 203087

I have 2 TDK switching power supplies, they are 5v @ 60A each. They have a voltage adjust pot, and I have been able to get them to go as high as 6.2v each. In a test, I combined them in series and got 12.3v out of them, but have not incorporated it into my shack yet because I want to make sure there's not anything else that I have to do.

Is there a proper way to combine switching power supplies (I've been told that it is possible, but they weren't sure how) and is it possible to modify each unit so that it can produce say 6.5 to 6.8v that way I can get at least 13v out of the two of them?? Anyone done this before?

Thanks in advance for you help!

Source record: 203089

I am attempting to hook up my TH-225A to a footswitch I made for my Alinco DJ580 and my TS-530. I can select input (headset, handmic, desk mic, etc.) and switching method and off I go. I can either key in-circuit (HT) or out of circuit (HF), but from what I can tell neither way will work with the 225?

I know the mic shield is normally isolated and when it is brought to ground the radio keys, but regardless of what I do I get no audio. A friend said that this radio doesn't do pull-down, it does pull-up, and using the switch circuit within the radio as the power for the mic, so I'm not powering the mic doing what I am trying.

If anyone could suggest something I'd appreciate it. The PTT is a real beast to keep held for ragchewing!

I have an Icom IC-900 radio, but no control head (and of course, Icom hasn't had these in years...) If you have a control head lying around, please let me know. If you know anything about the serial protocol between the head and the "A" unit (Icom doesn't know this either), I'd appreciate that too, since I don't mind hacking together a head.
Thanks very much.

I believe that meets the requirement. The requirement is only that
the user cannot change frequencies in normal operation to frequencies
where he is not licensed. So I expect not giving him the service password,
or requiring an internal jumper change not documented in the owner's manual,
meets that criteria. The FCC doesn't really expect the radios to be hacker
proof, that would make them virtually unserviceable.

>
>Jim

Ouch! No, Jim, I don't mean that at all. RF is an *AC* waveform,
electrons don't actually "flow" out of the transmitter. They
just vibrate back and forth passing the energy from one electron
to the next down the wire (Actually DC works the same way at initial
condition, IE you don't have to wait for an individual electron to
migrate the length of the wire to get current flow at the other end).
So this is not the concern. To visualize what happens, think of one
of those executive toys with the steel balls on strings, when you
pull one away and let it fall back, the one on the far end rises.
The *energy* has been transferred, but the individual balls are
still in the same places in line where they were. It's the same
with electrons in the wire.

But when we get to steady power flow, the current loop has to close,
or the energy has to radiate, one or the other. In an antenna, the
power radiates, in a transmission line the loop is closed through
the load back to the source via the other conductor of the transmission
line, or via some other unintended path. It's that unintended path
we are discussing.

No, that's different. Those stubs are part of the antenna and not
transmission lines.

>>>It is, instead, an unintended end fed 1/2-wave antenna. Now while it
>>>is true that the ends of such an antenna are voltage maxima, that's

>First it states that because the 1/2 wave shield simulates a 1/2 wave
>end-fed antenna, the voltage and impedance on both ends will be high.
>Then it says that because little current will flow, one end will
>actually be low.

No, it does not contradict itself, you've misread it (or I wasn't
clear enough). Because the impedance at the driven end is high,
not much current can be forced into it by a low impedance source
(the source is assumed to be 50 ohms because of the loading by a
dipole's center feed impedance). And because the impedance of the
outside of the shield at the other (transmitter) end is also high
(since the loop isn't closed) there will be a voltage maxima there
too, but it won't be much of a maxima because not a lot of current
got forced down the line, IE good old E=I*Z applies, and since I is
tiny, even though Z is large E is still relatively small.

In an ideal case, E will be exactly as large as it was at the driven
end, which will also be small since it came from a low impedance source.
In the real world, E will be even less because there will be finite stray
loading on the far end which will result in the tiny current being expressed
across a lower Z (but not a *low* Z if you catch my drift) and E=I*Z still
holds, but now *both* I and Z are (relatively) low and E will be even lower.

This is really a *power* flow, and we should be looking at that.
It would make things easier to explain. P=E^2/Z, and since Z is
very high at the driven end, not much power can flow down the outside
of the outer. At the transmitter end, the low power results in a low
voltage (the voltage is at a maxima to be sure, it's just that the
maxima isn't very max, again if you catch my drift).

>>>OTOH, a 1/4-wave will be a low feed impedance at the antenna, thus
>>>lots of current will divert down toward the shack, and will express
>>>itself as a high voltage at the high impedance of the other end.
>
>Another contradiction; this paragraph says the same thing about the
>1/4 wave shield that the previous paragraph said about the 1/2 wave -
>that one end will have a higher impedance than the other. This time
>it's true, but the rest of the explanation is incorrect.

No, it *doesn't* say the same thing. In this case, the driven end
is a *low* impedance, which matches the low impedance driving source,
so it accepts lots of power, and that power expresses itself across
the high impedance of the other end as a lot of voltage.

>>>(And the other end *will* be a high impedance because the current
>>>can't penetrate the coax shield or the transmitter case to "close
>>>the loop" with the driving source.
>
>This is also incorrect. The RF voltage at the antenna is a free agent
>that is attracted to *all* conductive objects with a lower potential.

I addressed this in another post that's already circulated. See more
in the response to that. Voltage is the *potential* between two
points, it is not a current, or an energy flow, it doesn't move
around by itself. It isn't drawn to things, it is what *draws*
charges.

I imagine Dean has tongue firmly in cheek here? Personally I'm against this recycling stuff, seems rather environmentally risky to me. All those batteries sitting in storage for some far distant day when someone discovers a use for them.

My advice is to not worry about it. Certainly it would be very rude to leave one's trash despoiling the wilderness. Just pack it out and throw it away. I buy AA and D size Duracells for use in my SAR radios and headlamps, and routinely trow away the dead ones.

But of course, we SAR sorts often pick up trash when we're out there. I only do this when hiking out 'tho, as I've more than too much to cwrry into the mountains as it is!

Scott:
Service monitors come with many features and directly
affect pricing. With the advent of Cell phone and trunking systems
many added expensive features were added. A used IFR-500A is about
minimal for Ham repeators. Sometimes you can find IFR-1000s for reasonable
prices. The spectrum analyzer accessory is a must. Tracking generators
are nice but not neccessary. An offset Oscillator really helps with
repeators. There are no new service monitors for under $5000 that are
really professional quality. Be CAREFUL with older equipment as mant special
parts were used and replacments are unavailble. I have had to rebuild
circuits where replacment parts could not be obtained. Try to avoid
any test equipment from the 70's, the transistors and IC's from that
era were not too durable.

That would be the limit of validity of that point.

The return path can be either "displacement current" or conduction
current. There doesn't need to be a ground plane or opposing conductor.

Feedlines and antennas function by the same principles. An antenna is a
leaky feedline, and a leaky feedline is an antenna. Any feedline without
EXACTLY equal and opposite currents in the conductors (including coax)
will radiate and behave (to some extent) like an antenna, and any antenna
of finite length must also behave (to some extent) as a transmission line.

I have both, and primarily use the 450 as a mobile/RV rig because of it's smaller size. Both are very good, but the 850 definitely gets the nod as a low noise receiver, and the ability to vary the passband response really helps sort out weak signals. Good luck with your choice - you won't be disappointed with either of them!

Ham Shack For Sale

1. Icom IC-736 HF Transceiver with 6m. 100 watts all bands inc. 6 meters. Built in power supply and antenna tuner. One year old. Mint Condx. $1400.00
2. Henry 2K Classic X 80-10 meter linear. Floor model. Legal limit output on all modes with pair of 3-500z. $800. This is too heavy to ship. Pick up only or will meet someone within 600 miles half way.
3. Icom IC-229H VHF mobile 50 watt output extended receive. Excellent Condx $275
4. Alinco DR1200 25w 2m fm data radio $225.
5. Alinco ALD-24t vhf/uhf dual bander $300
6. Dentron DTR-3KA 1500 watt HF antenna tuner. $150
7. Timewave Tech DSP 59+ DSP $220
8. AEA Morsemachine Memory Keyer and a whole lot more. $125
9. KPC3 Packet Controller $80
10. Bencher Chrome BY2 Keyer Paddle $75
11. Vibroplex Brass Racer Paddle $60
12. Ham Windows Plus Control and logging software..V 3.0 for SVGA $60
13. Welz 1.6-60 mhz 2KW peak reading power meter $75
14. Yaesu ys-500 140-525 mhz power meter $75
15. GAP DX-VIII vertical antenna 6 months old with counterpoise kit,, $225
16. Heil Headset with HC4 element and ICOM and KENWOOD connectors $85
17. US Tower TX-455 55 foot crank up tower with tail twister rotor, Hygain Explorer 14 Tribander 20 foot HD mast. Heathkit HD1780 rotor controller, KLM 2m and 430 satellite antennas, Yaseu elevation rotor. And Hygain 3 element 6m antenna. All coax and controller cables included. Will separate after tower is sold. Whole package $1900. Tower with mast $950. (This setup is about 7 years old). The tower and antenna's are still standing and I will need help taking them down.

For further information contact my via email ke0kb@primenet.com or call Tom at 612-529-8966

>>single-conductor decoupling stubs in microwave circuitry.

>No, that's different. Those stubs are part of the antenna and not
>transmission lines.

Actually, I was thinking about stubs used at the output of a mixer or driver, connected between the signal path and ground. Wes has called me to task on this point though and I think it's better left alone. The analogy may not hold, due to the proximity of those lines to a parallel ground plane.

>And because the impedance of the outside of the shield at the other
>(transmitter) end is also high (since the loop isn't closed)

No, it isn't high. I've explained this in three posts, although I don't know if you've received them all. One quotes ARRL literature which states that the impedance at the transmitter chassis isn't a high impedance point and that a 1/4 line from the antenna will detune the system for common mode current.

I basically agree with the rest of your post except for statements specifically related to this concept. We're splitting hairs on the subject of voltage; we both know what it is and what it does.

The power flow you mention does need practical consideration, but I think it's a side issue. Regardless of the total power, voltage or current can be high or low, depending on the impedance. It's those components that ultimately cause the symptoms we have to deal with.

Anyway, the transmitter chassis is not at a high impedance point in the typical ham shack. We should come back to this after you've had a

chance to read my other posts. One quotes ARRL material from the Antenna Handbook, the other is titled "The Transmitter Chassis". We won't be able to find mutual ground until we discuss the issues in those articles. No pun intended. ;)

>Let me see if I understand this statement. Are you saying, if I
>ground the far end of a half wave antenna, the current maximum STILL
>occurs in the middle instead of the end?

This is a *very* important point.

If a 1/2 wave end-fed wire is terminated with an infinite impedance (open ended), it exhibits voltage maxima at the ends. If it is terminated with zero impedance (connected to RF ground), it exhibits voltage minima at the ends.

Between these two values, there is terminating resistance for which there will be no standing waves on the line. The value of that resistor is equal to the surge impedance (Z0) of the end-fed wire, which is in turn determined by the diameter of the wire and the spacing of the wire above ground. When it is terminated with that resistance, the source will see that resistance regardless of the length of the wire.

In this regard, the wire behaves exactly like a transmission line.

520. Question abt 2m ant.

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-09 00:00:00 UTC
From: mouer@mail.ameritel.net
Message-ID: <497cc$11226.13b@NEWS>
Source record: 203107

I am planning to purchase a 2 meter portable (HTX-202) and maybe a mobile ant.

What is recommended, if it's even neccessary? 1/4, 1/2, 5/8? Is a magnetic
mount possible?
Thanks.

-Dan.

I have both the kenwood TS690 and the TS850. I like both but have to
agree that the TS850 is the way to go. Manufacturer specs don't mean much.
The QST/ARRL LABS test reports are much more meanigful. They found the
TS850 to have one of the very best recievers they ever tested - right
there with the FT1000D. As the other owners had mentioned the slope
tuning is a godsend on crowded bands. Good luck! --- Steve N9ROU

Has anybody ever heard a possibility to talk direct to somebody's ears/head from 200 kilometers away? What kind of equipment is needed for that? What kind of transmitter and receiver you would need for that to suprise somebody totally? The receiver at least should be as small as possible and not to notice easily.

What about radio waves genarally? What you need to catch them from the air? How is the right frequency adjusted? What kind of traffic in the air is possible to follow? Are there frequencies that are not allowed to listen. How is that prevented?

The typical HF transmitter case is not a high impedance in a car either,
or on the second floor, or anywhere except maybe sitting by itself on a
wooden picnic table. Of course the power supply would have to be a battery
sitting right against the rig!

Source record: 203118

Hi:
I am looking for some advice.
I plan on purchasing a linear amp. I am using an R-7
with under a 1:2 SWR match on all the bands I intend
to use. If I try to use a tube type linear, will the linear's
pi or pi-L matching section be adequate or will
an external antenna tuner be necessary. Currently, my
HF rig is connected to the R-7 with 8D-FB(I think it's
about equivalent to low loss double shielded RG-8).
Furthermore, I have a Bencher low pass filter, in the event
that I have to use an antenna tuner after the linear, should
the LPF be before or after the antenna tuner.(I assume that the
LPF is looking for 50 ohms termination)

Maybe you can help me with this question: there is a delay between the
signal that goes into the unit and that which comes out. When you are
sending CW, does that "mess up your timing" (if you send and hear the
signal slightly after you close the key?)

I know that there is a mobile unit made by ICOM, the IC-38A and an HT
from ICOM, the IC-03AT.

Personally, I find that the IC-38A is a bit limiting with the memory
arraignment but you might be able to work around it if there are not too
many different PLs being used in your area.

I had exactly the same problem with my FT-530. You need to upgrade the VCO
at Yaesu. It will cost $50.00. I sent mine in but haven't got it back yet.
It takes about 3 weeks. Just send it in to Yaesu service center with a note that
you want the VCO upgraded and you understand it will cost $50.00. Include your
name, address, & phone number.
Don't call and ask them about it? They will say they don't do VCO upgrades.
However when I called John Lynn (head of Customer service) he said they will do it.
Thanks to Kevin (wd6dih) for this info and John's name.

Scott:
Beldon 9913 is inexpensive, but it has some serious drawbacks.
First: it requires special connectors because the center conductor is slightly larger(9 gauge) than RG-8.

Second: Mechanically 9913 is rather poor. The outer braid is VERY fragile and makes poor connection to the connectors. I have used 9913 for several years and even with the supposed improved connectors have had connections break. The inner conductor is not located very well with the small plastic string and is uneven in its impedence.

The LMR series of cables are much better mechanically and are availible at most 2-way suppy houses.

If you need good transmission line use any of the available hardlines, they cost a little more for the cable and connectors but in the long you will have better connections and lower losses.

Any shielding that lets RF in, must also let RF out. Now I don't
know about you, but I'd be real upset with a transmitter that
leaked a lot of RF into the shack (if it did, I wouldn't *care*
if RF also came back down the feedline because I'd already have
a "hot" shack). So I'd suggest that any leakage either way is going
to be minute, which implies that the pathway through the shielding
is a very high impedance. If this weren't so, you could never get
a repeater to work since the transmitter RF would bypass the duplexer
and go directly into the receiver by the cabinet to cabinet path.
To get a repeater with -120 dbm sensitivity, those chassis had
better be cold on the outside, and they are, and they don't
require an Earth connection for that to be so either, as my
repeater located 970 feet above Earth testifies.

>For purposes of this discussion, assume we have a 100 watt HF

>the calculated value (E = sq root (P*R)) and that the voltage
>everywhere on the chassis is a very low value. This can be further
>verified by the fact that touching the center pin will cause a burn,
>but touching the chassis will not.

The inner pin will be hot, and the *inside* of the connector shell
will be hot. The *outside* of the shell, and the *outside* of the
chassis, will not be hot. This is shown by the fact that even a
low capacitance scope probe is sufficient to load the outside of
the chassis to a value very near the scope reference, IE scope
"ground". There is no need to involve Earth.

Lets allow that the transmitter is operating at 144 MHz where the
scope won't be connected to Earth with a low impedance path via its
third wire. Your measurements don't change, as anyone troubleshooting
a Micor can attest. So Earth isn't the magic here. Any coupling to/from
Earth for either the scope or the transmitter chassis will be high
impedance, yet the outside of the chassis still reads "cold" when
loaded with a low capacitance 10X scope probe. Why is that? Because
there is very little RF current flowing on the *outside* of the
chassis. Put the covers back on, and there will be virtually none.

>Now, considering that the AC voltage at the two output terminals of an
>isolated generator will be equal amplitude and opposite phase, how can
>the preceding be true? Shouldn't the flange of the connector (and
>thus the chassis of the transmitter) have the same RF voltage as the
>center pin? The answer is yes, it should, and if we perform the same
>test with a solid-state mono *audio* amplifier, we would find that the
>AF voltages on the chassis and on the "positive" output terminal are
>in fact nearly identical.

Yes, at *audio* frequencies, where *skin effect* doesn't come into
play, this is true. But at RF, where skin effect does come strongly
into play, the signal on the *inside* of the connector shell can't
get to the outside of the connector shell, or the outside of the
chassis. The thickness of those parts is several skin depths, so
their insides and outsides are isolated from each other.

I deleted the rest of your argument because it is premised on the
outside of the chassis being at the RF potential of the inside of
the chassis, which it isn't. If it were, you could take a transmitter
up in a balloon and draw arcs from either the antenna or the chassis
since there's no nearby Earth to unbalance it and make the outside
of the chassis cold. But you can't. The chassis is still cold up there
far from Earth too. But you *can* draw an arc from the end of *either*
leg of a dipole fed by that transmitter, showing that both the inner
and the *inside* of the outer of the coax are hot.

Then you obviously have two wires don't you? (both legs of the hairpin)
The key point to grasp is that you can't have a naked potential. There
must be *two* points to have a potential because that's what a potential
is, the work function difference between two points, IE

V=Q/(4*pi*eo*r)

That says that voltage (potential) is proportional to charge and
inversely proportional to distance, r. If r goes to zero, V becomes
undefined. So you need two separated points to have a potential.

Now F=-Q*E, where Q is charge and E is the field intensity, and
Vab=-integral from a to b of E*dI=W/Q, so a voltage is also a
Joule/Coulomb, IE a *force* per unit charge. For separated charges,
we have a force times a distance, which is *work*, so the potential
difference in a system is the work needed to move a charge from
point A to point B. Now a moving charge is a current, I, so a
voltage between A and B is the *potential* to move a charge from
A to B, IE create a current flow.

Eliminate B, and there is no longer a potential, and no longer
a current flow. Now a voltage difference forms a conservative system,
charge must be conserved, so we have Kirchhoff's law demanding the
current loop be closed with the same amount of current flowing out
and in the points while the voltages must sum around the loop to zero.

>>73,
>>Jack WB3U
>
>Ben Franklin couldn't have said it any better!

Except that Ben did say it better. He knew that only *charge*
moves, and voltage is what moves it. I expanded on this in
another post, complete with math. We cannot feel voltage,
we can feel currents driven by a potential difference (voltage).
We can't see voltage, we can only see the current flow (spark)
caused by the potential difference. And we can't measure voltage,
we can only infer its presence by measuring the current flow
it causes through a meter movement. All we can directly sense is
charge and its flow, just as we can sense a falling rock. We
can *infer* that something is making it fall, in this case
a gravitational potential, and infer the value of that potential
by the acceleration of the rock, but we can't alter or move
or measure the potential directly.

I ran this part number thru my ECG, NTE and SK cross reference programs.
Here's what comes back:

2N2156 = ECG213 = NTE213 = SK3012 = PNP Germanium/Hi Current/Power/TO-36.

Good luck,
Chris - N7RME

Source record: 202972

In 1958 the Viking Ranger sold new as a kit without tubes for 189.50. As I recall it could be purchased factory wired for $229.00. In 1968 I bought one used for $50.00. Back then it was just an "old" radio. Today it is probably classified as a "nostalgia" item. If it has been taken care of all of these years it should still look fine and and work excellently. It may be worth considerably more than the "old" radio price. It is a fine, durable, AM & CW transmitter,with excellent audio quality. I had mine on the air last winter on 160 meters with a local AM nostalgia net. It is still a lot of fun. It is worth what you can get! Caveat Emptor - let the buyer beware.

I have talked to customer service at Kenwood. If it is not a low nicad battery problem, it may be the mounting of the LCD itself. If you are confident in opening your radio, make sure that the LCD is seated properly to make a good contact.

If you have any doubts at all, send it in under warranty and the Kenwood techs will do it for you.

In many parts of Europe and 'authoritarian' countries in general, it may in fact be illegal to own and/or operate radio _receivers_ capable of operating on certain bands.

In the USA, it is unlawful to import or manufacture a radio receiver capable of intercepting cellular telephone frequencies- there are also restrictions on the interception of cordless phone conversations.

Until these laws were passed, all radio transmissions were fair game- the only limitation being that in some instances (such as police broadcasts) it was illegal to retransmit or otherwise convey the content of the conversation to others. E.g. you can listen in, but you can't transcribe what you hear and tell your friends.

I am trying to decide between the Kenwood TS450 and TS850. I work primarily DX and am primarily interested in receiver performance. From the specs, there does not seem to be much difference. Is the extra cost of the 850 worth it. I would greatly appreciate any comments

I have had an 850 four two years now, and I love it. I looked closely at the 450 when I was making my decision, and concluded that the 850 was a much better radio, for only a little more money.

The quick story: the 850 has a fine receiver. Before the most recent crop of $3000+ DSP radios came out, the receiver on the 850 was as good as anything else available (possibly excepting the OMNI VI). Additionally, the 850 is a superb radio for CW work (my primary interest).

The receiver in the 450 is not nearly as good. See the QST review for details, but basically there is a problem with intermod -- the receiver's intermod performance is quite a bit worse than the figures would indicate.

Finally, I second the comment someone else made regarding the slope tune -- this is a wonderful feature and worth the extra money all by itself.

YAESU ANNOUNCES THE NEW FT-50R DUAL-BAND HANDHELD

Yaesu announces the latest in dual-band handheld technology with the
release of the new FT-50R Dual-band handheld transceiver. This engineering
achievement offers features never before found in this small palm sized
handheld radio, rugged weather resistant construction with a full 5 watts
of power output. Exclusive INDUSTRY-FIRSTS found only in the FT-50R
dual-band will
enhance your operating pleasure. Super wide-band Receive coverage to 999*
MHz, Keyboard or PC Programmable, Rugged MIL-STD 810 Rated, CTCSS and DCS
(Digital Coded Squelch), distinguish Yaesu as the world leader in amateur
radio products.

FT-50R FEATURES

Super Wide Multi-band Receive for the scanning enthusiasts 76-200,
300-540, 590-999* MHz
(*Cellular blocked)

3-Selectable Rx modes AM, FM-Narrow (N1), FM-Standard (N2).

Rugged MIL-STD 810 Rated for Shock and Vibration.

Auto Range Transpond System (ARTS) uses DCS to automatically poll other
stations, indicating if they are within simplex range.

Digital Coded Squelch (DCS) is used in the commercial industry, DCS
provides 113 unique codes in addition to the standard CTCSS tones.

112 Memory Channels each stores offset, CTCSS/DCS & power output level.

Alpha-Numeric Display up to 4 characters may be used to name each memory channel.

Digital DC Voltage Display monitors current battery voltage.

Full 5 Watts Power Output with 4 selectable power levels.

(FT-50R available in both 2 and 5 watt versions).

Automatic Tone Search (ATS) scans for DCS and CTCSS* tones. (*w/ FTT-12 installed)

Receive and Transmit Battery Savers built-in.

ADMS-1C Windows PC Programmable (available June 1996)

Direct FM improves voice quality and permits DCS operation.

High Audio Output new technology and high efficiency speaker design produce super loud audio output.

Keyboard and Menu Programming allows for simple FT-50R operation.

This is not true. It is unlawful to import or sell a scanning receiver;
scanning receiver in this context means 4 or more channels. You can
build a receiver that doesn't scan and the ban wouldn't apply.

This is off the top of my head after reading Part 15 a few months ago.

Signal delay and CW sending

Yes, it is very difficult! Best to turn off the rig sidetone and listen to your keyer. The JSP DPS units have a transmit delay defeat feature; the DSP is disabled by a signal from the keyer to the DSP unit, or maybe it is from the rig, but anyway, the idea is to defeat the delay while you are transmitting by shoring out the DSP path.

567. I built a Johnson Viking II

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-10 00:00:00 UTC
From: Jim Reid <jreid@aloha.net>
Message-ID: <316C5796.28D2@aloha.net>
Source record: 202991

I built up a Viking II from the kit; it was April 1952, while I was anticipating graduating from High School in a couple of months. I had been using WW II surplus ARC-5 stuff on 40 CW since late 1950 as W6KPI. The Viking kit and manual were far superior to any of the later Heath Kit rigs. And the Viking was built like a tank, and with better TVI shielding than any of the moderen rigs! Because we were very afraid of TVI in the early 50's as TV sets were terrible in that regard. I initially was rock bound on 40, ie used crystals to set the frequency until I could save of the 39.95 for the Viking VFO kit, which was also very well done and fun to build. I built up the Viking II in exactly 40 kit building hours, as I kept track of the time in the assemably manual as I went along; a habit I carried on into my 37 year EE career in industry in my engineering notebook.

If I ran into a clean Viking II now, I just might buy it for nostalgia sake. I sold mine shortly after getting married a few years later, but did also build up the Viking Ranger kit; but I was disappointed in it compared to the Viking II.

> Chris - N7RME

Chris:
I have found NO "N" connectors that gave satisfactory results, due
to mechanical problems. Some of the PL-259 types have larger holes in the
center pin than others. On the smaller ones the center conductor of the
9913 is too large to fit without some modification. When using 9913 outside
be sure that the connectors are taped and water tight. The water can literally
fill the transmission line. The problem on the connectors is that the outer
braid is so flimsy that very little of it comes in contact with the connector.

If you have run some non-switching supplies in series, switching supplies shouldn't be any different. I have run 2 10 amp 12 volt switchers in parallel for my 20 amp hf rig. It should be fairly simple. 73, Good luck, Will. N1PXA

Hello.

I have an IC-T41A 440MHz handheld transceiver that also has VHF receive capabilities. Well, it used to. It now is totally deaf on VHF. It seemed to happen suddenly.

Does anyone out there have any experience with this radio or, more likely, its 2-meter cousin, the T21A? Might there be something obvious to check like a severed antenna connection that I could open up the radio and fix?

Just want to see if there is any useful advice out here before I send it to Icom.

Thanks and 73.

Message-ID: <8BE659D.0409000C99.uuout@cheaha.com>
Source record: 203001

Well, I've been SWLing for a while with a slightly aged Hallicrafters S-120 and the bug has finally got it's grubby little pinchers firmly attached to me and my billfold. I've been looking at getting a new SW receiver. I've also been thinking about getting into HAM. I don't want to go out and put four or five hundred bucks down for a receiver and *then* get a transceiver a little later. I've seen a lot of rigs that includes a general coverage receiver and was wondering if someone could point me in the right direction on the TX/RX combination. I've been studying the code for about a week, and slowly it's coming to me....got 3 steps under my belt.....I know I could get the no-code, but it's just not what I want. :)

Any info or advice would be most appreciated.

Thanks,
Take care,

Ed Welch

>>comments
>>
>>73 and Thanks in advance
>>KJ7GU, John
>>

Your right! Very little difference in receiver specs in comparison.
However, my money is on the TS-850S! There is about a $300 difference
in sales price.

Here is the $300 worth of features.

Electronic Keyer
Variable speech and noise blanker
slope tuning
Quick memo
monitor for tx audio
dim for display
digital CW recorder/playback
optional- Voice recorder
audio- Hi boost

If your into DX, and want a competitve edge, get the TS-850S. If your
on a budget and you want a radio that will work for all your ham needs
get the TS-450S.

Just my .02 cents worth

From: Peter Shintani <shintani@tv.sony.co.jp>
Subject: Help me, do linears need antenna tuners ?

Hi:
I am looking for some advice.
I plan on purchasing a linear amp. I am using an R-7
with under a 1:2 SWR match on all the bands I intend
to use. If I try to use a tube type linear, will the linear's
pi or pi-L matching section be adequate or will
an external antenna tuner be necessary. Currently, my
HF rig is connected to the R-7 with 8D-FB(I think it's
about equivalent to low loss double shielded RG-8).
Furthermore, I have a Bencher low pass filter, in the event
that I have to use an antenna tuner after the linear, should
the LPF be before or after the antenna tuner.(I assume that the
LPF is looking for 50 ohms termination)

w8jitom@aol.com (W8JI Tom) wrote:

>Let me see if I understand this statement. Are you saying, if I
>ground the far end of a half wave antenna, the current maximum STILL
>occurs in the middle instead of the end?

This is a *very* important point.

If a 1/2 wave end-fed wire is terminated with an infinite impedance (open ended), it exhibits voltage maxima at the ends. If it is terminated with zero impedance (connected to RF ground), it exhibits voltage minima at the ends.

Between these two values, there is terminating resistance for which there will be no standing waves on the line. The value of that resistor is equal to the surge impedance (Z0) of the end-fed wire, which is in turn determined by the diameter of the wire and the spacing of the wire above ground. When it is terminated with that resistance, the source will see that resistance regardless of the length of the wire.

In this regard, the wire behaves exactly like a transmission line.

2m radio at a local ham-fest. It looks to be an antique, so of course it had no accompanying documentation. This is an *old* tube-driven rig, no tuner, rollaway cabinet, etc. It has been retired from Civil Air Patrol use, so it still has CAP crystals in it.

If you know anything about this radio, have some info in the bottom of your file cabinet, or maybe have an anecdote to share, I'd sure like to hear from you.

Please respond via e-mail if possible (I'll repost), as I don't quite have the bandwidth to keep up with this newsgroup.

Thanks in advance.

All tube-type Amateur amplifiers will easily match a 2:1 SWR. You're correct about the filter - it needs to see the correct termination to ensure proper filter response. However, I don't know how much its performance will be affected by 2:1 SWR. That's certainly not very high, so the filter may work fine at the output of the amplifier. The best source of authority on this is the manufacturer of the filter.

>FT101E

Are you sure you want to do that? The 6146 won't handle as much peak current as the sweep tubes and the power loss is not insignificant. Without digging out my old schematic, I'll hazard a guess and say the FT-101E produces about 600V B+. That's not enough to achieve full output from a pair of 6146's and I think this is why Yaesu used three tubes when they made the switch in later models.

Incidentally, the 6146W has a 25 watt plate dissipation rating, compared to 35 watts for the 6146B.

Some OLD cell-phone (the portable type) can be modified
for the 1Ghz band but it is not easy. Some VE2's did it.

The new models are very difficult (impossible) to modify:
Surface mount.
Power Modules Hybrids designed for Cell Phone bands can't be pulled
to higher frequency without dropping dead, etc..

Mr kc5afm No question is stupid, just the answers !

Source record: 203145

I purchased one in January and mounted it in my pickup. It was a replacement for my TS140 which took up too much space. The radio works very good. My only complaint is the short (~5 feet) control cable. I ended up buying a second cable and making an adaptor to plug two cables together to allow placement of the main chassis behind my seat rather than under it. Alinco claims that a longer cable than they provide may cause problems with signals from the head to the radio as the only microprocessor is in the head. So far, after about 6000 miles, I have had no problems and I would recommend the DX70. If you need to put the radio in the trunk of a car you may want to look at the Icom 706, it has a longer cable available.

Sorry to rain on your restoration project, but you will have a VERY
difficult timer finding these meters, and rightly so. The original meters
utilized a "glow in the dark" radioactive phosphor dial paint. DoD
required all R-390 users to place radiation warning labels on the front
panel of every receiver next to the meters. Further, when these receivers
are taken out of service, the user is required to remove the meters and
send them to a low-level radioactive material disposal site. It is not
possible for the average civilian to remove the radioactive paint and have
a non-radioactive working meter movement.

There may be more truth in your post than realized at first glance. Ham radio now is not much different now than CB used to be!

When I was about ten years old (1960), there were three Hams and two CB'ers in my small rural neighborhood. Both CB'ers built their own rigs, receiver's and all, from scratch. The Ham's both built a lot of stuff too, but not receivers. All of them spurred the interest of a few neighborhood kids better than Wayne Green, the ARRL, or W5YI ever could.

Now we'd be lucky to find five people in a major city with home built equipment.

Maybe things have gotten too easy, and the magic is gone. Maybe that's why Ham radio is boring? Maybe it's because anyone can do it, it's like a telephone.

In keeping with that thought, I think the best transmitter and receiver is anything you aren't afraid to work on. And especially it's one you build yourself. A one tube (or transistor) CW rig and a super regen receiver are better than a FT1000D in my book.

>73,
>Jack WB3U

Hi Jack;
Boy I have gotten a stack of the OO notices in the last twenty years. All
concerning my chirpy signals. I have never gotten one from the FCC.
Sometimes I think I should apply for a Cuban callsign so I will quit
getting the notices. Now don't all you people get upset and think I am
slamming the Cubans. There is a good reason for their chirpy signals.
The Cuban stations generaly don't have the luxery of stable 60 Hertz
power. I would challenge any station to try running a tube rig on power
that runs from 50 HZ to 70HZ and not sound chirpy.

Thanks for the hint on the Omni 6. I have operated the Century 21 and it
was a nice rig. I almost bought one but my cousin traded it in for a TR4 CW
The Ten Tecs have nice QSK features. I haven't run accross many of the
TEN Tec rigs at hamfest. They must have lots of happy owners.

From: ham@w3eax.umd.edu
Message-ID: <4kgj5r$qfq@cville-srv.wam.umd.edu>
Source record: 203153

I ran into the Sales Manager when at the Timonium hamfest.

The DX-70T's CW filter doesn't sound particularly sharp
because it's a CERAMIC filter as opposed to a crystal
filter. Apparently, they couldn't get a crystal lattice
filter small enough to fit inside the radio.

It works pretty well, but is not a lattice filter; you can
tell.

He also avowed no knowledge of the radio being able to
go up to 2m, although people claim there's something
like "144" on the PC board....

There are plenty of self proclaimed "experts" around here....the key
is to be able to recognize these guys and filter out the ones who think
they know it all from the ones that are truely knowledgeable.
You will discover that many of them are the ones who reply to every post
with their opinions. The desireable responses come from those who do
more reading than writing...names that you don't see posted everyday.
I learned a while back that it is wiser to do more listening than talking.
(That is not to say that you shouldn't offer to help when you can.)

>

I have owned both radios.
Big difference in receiver performance between the 850 and 450.
The 850 has a lower noise floor, noticeably better dynamic range
and noise filtering (slope tuning as mentioned above).
The 450 suffers from front-end overload when band activity is high,
especially on 20 and 40M. (I have not noticed this on my 850.)
The 850 also has some features that make DXing and contesting smoother
like a built-in CW keyer, optional voice recorder-playback, 2 levels
of RX attenuation, ect...
The tuner also works from 160 to 10M whereas the 450 tuner does not
cover 160M.
I believe you would be much happier with the 850 !

An electroluminescent panel is used for the backlighting.
It is a thin flexible plastic covered piece that is removable from
behind the LCD display. you can order them from Tandy National Parts
(don't have the number handy...call your local R/S).

Here iz what I got....

>| Yaesu FT-840 Expanded RF
>| All band modification:

1. Remove ant from radio.
2. Remove top and bottom covers.
3. On Local Unit , TEMPORARY jump TP-2003 to ground.
(Take a wire lead + attach to the metal case)
4. Press & Hold (SSB) + (AM) and turn power on.
(Display will show 02-OFF)
5. Rotate main control to show 02-ON
6. Press AM. The display should read (7.000.00 LSB)
7. Turn radio off.
8. Press and hold the memory (DOWN) + (UP) buttons and turn radio ON.
9. Turn the radio OFF.
10. Remove the jumper to ground on TP-2003.
11. Reassemble radio.

Think u were missing step #6. Mod taken from Book 8A
Gud luck.....hope this helps....dave

From: G7MRI@GB7LWB.#27.GBR.EU
To : YAESU@WW

Well guys i see that many people have been looking for mods for
this radio so here is the out of band tx mod.

1. take off bottom and top covers.
2. connect a jumper from point TP2003 to ground. this is temporary
while preforming the programming steps. that point is in front and to
the edge of the lithium battery.
3. with the ft-840 off, press and hold the (SSB) & (AM) buttons at the
same time. turn on the rig, then release the buttons simultaneously.

4. the display will show (02-ON). press the (AM) button to confirm
setting: it should read 7.000.00 LSB. turn rig off.
(If the rig does not show 02-on move the main freq knob to change it)

5. press and hold in the MEM , (DOWN) and (UP) buttons while turning
rig "on".
6. turn pwr off, and remove jumper.
7. if you have a problem, dump the backup memory by switching the back
up switch off per the manual.you can then redo the steps.

If you know of any mods please let me know and if you can find out what
01-ON/OFF to 09-ON/OFF i think it goes to, what do the other settings do.

73's de John
G7MRI@GB7LWB.#27.GBR.EU
~~~~~~

The mod below was the only mod for the FT-840 that I could find on the net.
THE MOD BELOW DOES NOT WORK!!! It is listed here for reference only.
Archievers might want to remove this mod if they have it.

~~~~~~
From: paul@theborg.mlb.fl.us (SysAdmin)
Subject: FT-840 Expanded RF Mod
Date: 10 Dec 94 08:02:20 EST

I saw many requests for this mod but never had a chance to post it till now.

Yaesu FT-840 Expanded RF
All band modification:

1. Remove bottom cover and locate vertical pin TP 2003.

2. Connect a jumper wire from this pin to ground.

3. Hold SSB button and AM button at the same time and turn the radio On.

4. Frequency display should read "02 OFF". Turn Frequency knob until display
reads "02 ON". Now turn radio Off.

5. Hold VFO/M button and UP and DOWN buttons at the same time and turn the
radio On.

6. Last, turn radio Off and remove jumper from Test Point 2003.

7. Reassemble radio.

This mod allows gerneral coverage transmit on the FT-840.
I assume no responsibility, proceed at your own risk.

If you are thinking about using you PC to control
you ham rig check out my page and the FT-736R CAT
section. The unit shown is usable on all rigs that
require a RS-232 to TTL level converter to control
the rig. Kits include all connectors needed for
connection to Kenwood, Yaesu or Icom rigs and as
well as others.

Check it out ...

Nothing but good things to say about mine. Great Rx sensitivity. Extended Rx range. Transmits good sounding audio (according to the people I talk to). The sales man said the user interface was easier on the Kenwood T22, but I didn't have any problems learning the Icom.

> Also, what features should I be looking for in a handheld unit in the

> and tone squelch features actually *do*, so any help in that area would
> be appreciated.
>
DTMF (Dual Ton Multiple Freqency) is for creating the tones for dialing telphone numbers, like through an autopatch. Many repaeters have additional controls, like linking to other systems, that can be controlled by DTMF tones. I would venture to say that most, if not all new HTs have DTMF capability.

Coded squelch uses those DTMF tones to open up preprogrammed receivers. The receivers will only open the squelch after hearing the tone sequence you've programmed. This can allow many people to use the same simplex frequency without hearing each other (not at the exact same time however). This is popular with commercial radios, but I haven't heard anyone using it in the 2m band. It is an option on many radios.

Tone squelch uses a sub-audible tone (aka PL tone) to open the squelch of the receiver. This is something that is used alot in repeater operation. A tone, anywhere from 50 to 300Hz, but usually around 100Hz, is transmitted along with your voice. I don't know if the IC22A can use the tone on it's receive (it has some tone scan feature for figureing out what tone a repeater is using), but it can transmit the tone. I think any new radio can transmit a PL tone.

>positions in step with the changes in potential.

Gary, explanations like this are the reason your readers are confused, and perhaps also the reason we are having this discussion. What you've said is true, but it falls far short of explaining the flow of current that Jim asked about.

It is much easier to understand what's happening if it's remembered that the transmitter has two RF output terminals (poles). The only "loop" that must exist in order for current to flow is the current path internal to the transmitter and through the load. To satisfy Kirchoff, the current flow through all internal points and through the two output terminals must be the same.

What you've missed is that current drawn from those two poles is forced to be equal and opposite by the inherent nature of the fields inside the coax. Therefore, regardless of the load at the far end of the coax, the load seen by the transmitter itself is *always* balanced at both poles. Nothing is attempting to draw more current from one pole than the other, therefore there is no need for any "return" current in order to balance the transmitter. **This condition is satisfied whenever coax is attached to the transmitter.**

Please stop this nonsense about some sort of external loop that must be completed. It is an instinctual concept that does not exist in a coaxially-fed system.

>filter small enough to fit inside the radio.

Then where does ICOM get the 500hz and 250hz filters for the 706? Doesn't
the TS-50 (a very nearly identical box) have a narrow filter option too?

Alinco advertised it as having a 500 Hz cw filter. I measured the
response on mine, and it's about 1.6 khz wide at -6 db. 500 Hz cw
filters have been a pretty standard quantity on ham rigs for the last 10
years or so - if they weren't going to include one, they shouldn't have
advertised it as having one. I can't think of any way you could
characterize what they have for a narrow filter in there as being 500 hz
wide - unless you measured at the -0.1 db points maybe. Saying it had a
500 hz cw filter when in fact it doesn't is pretty low. A lack of a
narrow filter isn't an insignificant issue - it's important for anything
but the most casual cw operating, and very useful for digital modes.

It was instructive reading the review that 73 mag gave it - they
mentioned something like the 'sharp cw filter', blah-de-blah. By that
point I'd already talked to Alinco and found out about the bogus filter.
Reading over the section in the review on cw operating and the glowing
report, I realized the reviewer apparently never opened the box. The QST
review in comparison did point up the problem.
>
>It works pretty well, but is not a lattice filter; you can
>tell.

To me it just sounds like a hi-cut, as if they had tacked a cap across
the audio channel to drop a little of the high frequency hiss. If you
listen to a croweded frequency and switch the narrow filter in and out,
you can still hear all the signals, but the background noise changes. :-(

☐☐You could put a better *audio* filter in than what they have - even the
cheap little RS DSP box has much better filtering in it's cw mode.
Unfortunately adding an external audio filter for CW adds another box of
near equal size - nullifying the whole concept of a small
multimode/multi-role radio.

Bottom line, it's still a good radio for lots of other uses - it has a
decent receiver and always gets good audio reports on transmit. But if I

had had the truth when I was making the selection, that there really wasn't a 500 hz cw filter and no possibility of installing one optionally - I'd have made another choice. Now I have to read all advertising from Alinco with a big grain of salt. Fooled me once....

I was given a Motorola PC10 vhf ht that is in the business band
and have some questions in regard to making it useful to me.

1. Can this radio be made to work on 2 meters?

2. The radio contains a 7 pin connector (I presume for programming)
Is the pinout / protocol / software available to reprogram this
radio?

3. Can the radio be programmed for 600kHz splits? (It's simplex now)

4. There are 4 switches inside the radio. What are their functions?

Thanks in advance for any help.

I'll second the Omni VI recommendation. I've owned one for just over a year, and it's a fantastic CW radio. The receiver is superb, especially in pulling out weak signals VERY close to strong ones. QSK has always been one of Ten-Tec's strong points and works beautifully. The CW filters work very well (I highly recommend the 500 Hz first-IF filter, along with the 500 and 250 Hz 2nd-IF filters). If you want to work portable occasionally, the rig has a good internal keyer (Curtis A or B type, selectable), and runs on 12v. You can connect the internal keyer and an external key closure (e.g.memory keyer or computer) simultaneously. It's also a very good SSB rig -- not quite as many bells and whistles as some, but very good. There was a favorable review in January '93 QST, and a couple of the minor points have been addressed since then: the crystal oven is on whenever 12v is applied; and the tuning rates (main, RIT, and XIT) are now programmable.

I think this is very close to the ultimate CW rig these days, but on the other hand my Drake twins are still working great, too, and I doubt I'll ever part with them. And those little QRP rigs look like a lot of fun, too.

Hi,

I have recently obtained an Icom IC-125 High Band PMR radio, which I intend using for 9k6 linking. It is a 5 channel, diode-programmable synthesised radio of the upconverting kind, so should give excellent BER performance.

I believe I need to change crystal X2 to 40.2166 MHz and retune to get it into the 2M band, and fm X1 (21.4 MHz) with a varactor for modulation.

Does anyone have any experiences of this set, and I would *really* appreciate a copy of the circuit diagrams etc.

Here's hoping ;-)

Steve

>and this is antenna current, not transmission line current.

First, I disntinctly remember an implication by you in a reply to Tom
that the single conductor had no characteristic impedance. Does your
answer above mean that you now accept the statement that it does?

Second, I did not say there would be no standing waves on the shield.
However, regarding standing waves, your misunderstanding of this
mechanism is very evident from your reply to Tom in another post. You
were asked "if I ground the far end of a half wave antenna, the
current maximum STILL occurs in the middle instead of the end?" Your
answer was "Yes".

What you have failed to consider is that if the terminating impedance
is higher than the surge impedance of the shield, standing waves will
create voltage maximas on the ends of the shield. If the terminating
impedance is lower than the surge impedance of the shield, standing
waves will create *current* maximas on the ends of the shield.

In between an open and a short, the impedance at the ends of the
shield will be some intermediate value and this is why the 1/2 wave
shield does *not* present the high impedance of an open-ended antenna.
Rather, it reflects the common mode impedance at the transmitter back
to the source.

> The error at 2 is your error. You're trying to apply a special case,
> a matched line, to the general case of a mismatched line.

No I'm not. You're reading something into my post that I didn't say.
I'm hoping this is because you're beginning to realize that what Tom
and I have been saying is true. It would be nice to reach a
consensus. ;)

> You're falling into the trap of implicitly assuming a matched
>termination for the currents on the outside of the outer conductor.

One of my earliest posts in this discussion mentioned standing waves on the shield. I *never* said the line was flat.

>In fact, Earth is extremely unlikely to provide a matched termination
>to this current, wave reflection will occur, and the behavior of
>currents and voltages on the halfwave section will be similar to
>those found if it were operating in isolation, IE the normal antenna
>current standing wave pattern will exist.

You're completely missing the fact that the impedance at the ends of a 1/2 wave wire will depend almost entirely on the nature of the termination and the degree of mismatch.

>Incidentally, that's why a halfwave vertical worked against ground
>has a very high base impedance, and you have to tap up on it with a
>shunt feed to match a 50 ohm coax to it.

If you terminate the far end of the vertical with a resistance to ground, the base impedance will be reduced accordingly. That's why your statement that the shield exhibits the same impedance as a 1/2 wave open-ended antenna is completely untrue.

Gary, at one time you stated that the reason for the high impedance was that the transmitter represents an open-ended wire. Now you're arguing that a 1/2 wave wire will *always* exhibit voltage maximas on its ends, just like an antenna, regardless of the termination. This sounds as though you have no evidence to verify either statement and you've simply presented them both in order to hedge your bet. ;)

73,
Jack WB3U

630. Need mod for IC735 noise blanker

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-11 00:00:00 UTC

Hello FT736R owners (inc. me),
In the Proceedings of the 21st Eastern V/U Conference (available thru ARRL) there is an article by Bruce Wood N2LIV and Ron Katz WB2DVK on "revitalization of the 736." It describes entirely new front ends for the xcvr. These are commercial front ends. Noise floor, NF, and dynamic range were the areas of improvement. I have not bought these.
I am a bit disappointed in the features of the rig. Even my FT650 had a built in attenuator! Also seems like a rig in this price range would have xvrtr outputs and the ability to turn OFF the AGC. Hard to measure sun noise when the AGC is always on (I don't need 3 different AGC speeds).

>=Vic=
>WA4THR

Vic's quite right. Any PA with an adjustable nework doesn't care what the
load SWR is, as long as the network can still tune correctly.

A high SWR doesnt make tubes wear out, and doesn't necessarily make the
tank get hotter. It is as likely to make the tank run cooler as hotter!

The only real worry is if the voltage of the loading cap is exceeded, or
the thing just won't load.

Hi Peter;

If your antenna presents an SWR below 2:1 the typical tube linear pi net will suffice. As to low pass filtering the connection of the filter is after the source of high order harmonics that you wish to suppress, but since the filter has a given impedance - probably 50 ohms- it goes before the tuner. It must be capable of the full power output from whatever is driving it. If you only have a 100 watt filter available you must put it after the exciter and before the amplifier. It will suppress the harmonics originating in the exciter. Most filters and tuners are rated for continuous RMS power. The average power in a SSB voice wave form is typically at least 10 db below the peak, so unless something arcs over from voltages on the peak, and tells you immediately that you have a problem from peak power levels, you probably will never have a "burnout" from overheating.

You might want to add point #6, which is that most scanners, which are
"incapable" of receiving cellular, can still pick it up when tuned to
frequencies outside the cellular band. The filtering is not adequate to
suppress the reception in "image" frequencies.

LHI POCSAG Decoder

Pager data stream monitoring unit

L0pht Heavy Industries is proud to announce the release of our POCSAG monitoring unit. Used in conjunction with a radio scanner or receiver, it allows off-the-air decoding of POCSAG paging signals at 512, 1200, or 2400bps. Both numeric and alphanumeric messages will be decoded, as well as a hex dump of raw POCSAG codewords.

This system is useful for the testing of paging systems and transmitters. With the included software, one may reject or log to disk specific pager capcodes, making it easier to track only the necessary signals. The device is powered off a PC-compatible serial port and is extremely small - handy for portable use.

The unit is available in both kit ($59.95 + s/h) and fully-assembled ($89.95 + s/h) versions. All components, schematics, software and documentation are included. Fully-assembled units are tested before shipment. General soldering and electronics knowledge is required to construct the unit from kit form, so please be aware when ordering. LHI is not responsible for any results, good or bad, produced by the user during use or construction of the product, so consider the assembled-unit if you are not confident in your assembly skills.

Name: _____

E-mail Address: _____

Mailing Address: _____

_____

City, State: _____

Country, Postal code: _____

Number of units: _____ Circle one: KIT ASSEMBLED

Amount Enclosed: _____

To:

POCSAG Project Division
c/o L0pht Heavy Industries

P.O. Box 990857
Boston, MA USA 02199-0857

Please include $59.95 for kit-form or $89.95 for fully-assembled unit plus $5.05 for shipping and handling in United States currency for each unit ordered. We will ship all orders via First Class United States mail to anywhere in the World. Cash, Check or Money Order accepted, sorry no Credit Card orders. Please make all checks payable to L0pht Heavy Industries. Massachusetts residents please add 5% sales tax. Please allow four to six weeks for delivery.

L0pht Heavy Industries (L.H.I.) assumes no liability for lost or misdirected mail. LHI reserves the right to refuse sale of this unit to any person, organization or entity. All sales are final.

Any questions can be directed to pocsag@l0pht.com

A friend is wanting to know what mods there are for the DJ582. He has both a 582 and a 580, but the 582 has different coloured wires and he wants to be sure he's cutting the correct wires.

I assume he wants both tx/rx.

Thanks

>respond to the mail that you sent me, you had the bad tast to push the
>issue and repost what you sent me in private to this public forumn.

Wrong, I always post via "post reply" and email, they go at

the same time. Bad taste has nothing to do with it. In some

groups post dont always make it in tact email almost always

does. Lets just call it diversity transmission. This is
being posted in the exact same manner (check the times in
the header).

>>Was Internet your first contact with the REAL world???

>I have had lots of contact with the real world, and the internet is
>not it.

We''ll if you followed this whole thread and walked down the
streets of some large cities or went into a bar, I would say
the the same diversity of personality types would exists,
unlike in some small town (or small countries) where almost
everyone thinks the same.

>Sad that you think it's the real world. The tone and style of
>your messages suggests to me that you need more real world face to
>face interaction with people.

No I just get fed up with self righteous people who get holier than thou for no good reason.

Look, hereis the situation; Yest the original poster probably wanted attention, thats obvious. But beyond that he is typical of so many creative people I deal with everyday. His little pirate radio transmitter has an intermittant problem. He obviously had some great vision of what he would do with it and being more creative than technical lacked the analyical ability to define what the fault really was. Because this was a deeply emotional event for him he expressed it the way he did. I hear program directors and on air radio talent do the same thing every day.

The bigots reject him more because of what he represents than what he said.

As fhe crap about 11 year olds, etc. listen to them talk some times, like wise for some people's mothers, etc. etc. What they really do like is the mental mode of the poster, in other words discrimination.

As for the excuse that it was crossposted. An FM 25 is not remotely cosidered any kind of ham gear, so regardless of where it went I still submit that they are responding to alt.pirate.radio where the post is not all that big of a problem.

Rob

>scanning receiver in this context means 4 or more channels. You can
>build a receiver that doesn't scan and the ban wouldn't apply.
>This is off the top of my head after reading Part 15 a few months ago.

I believe you are in error. The law was put in place to prohibit unathorized tapping of Telephone Conversations. If you were to listen to a Cell conversation, this would constitute tapping of the line as only a small portion of the conversation is actually on the air. The rest is on copper or fiber. This is the same with cordless phones.

Your statement about scanning rcvrs is also incorrect. I can order a rcvr with full coverage from 100khz to 1.9Ghz (except cellular bands) with 1000 channels. I did it this year when I purchased an AR8K. The loophole is manufacturing the scanner. It states the unit cannot be easly modifable. Yet multiple ads in magazines offer 800Mhz restore for $40-$50. Obviously, a loophole or just not being inforced. I purchased software and an interface for the 8K and all I had to do was click a button on the screen and put the unit in download mode. Real easy if you ask me. The law as it stands is esentially a joke. Many double conversion rcvrs will pick up cell when legal freqs are plugged in and scanned. Does this constitute as a violation of the law??? I had a RS PRO-39 and while at the sceen of a suspected bankrobber hold up in an apartment. I heard the FBI talk about the suspect, I was scanning legal trunk freqs. Am I a criminal because I heard the conversation, NO! But IF I were to use that info maliciously and it could be PROVED that I got it from the scanner then YES I would be committing a crime. Also, the conviction of the man how modified receive only trunked radios to receive other talk groups than the police dept had placed in them for the media was reversed. (can't remember source, maybe MT or USSN) There are more laws that apply to scanning than part 15, try the ECPA.

Does anyone know if a newsgroup exist where HDTV issues are discussed?

If not, I figured our amateur radio newsgroup would be the best place to post a technical question about the impending HDTV broadcasting changeover...So here it goes....

The projected cost figures of the HDTVs are extremely high compared to current TVs. I suspect the majority of american families will be unable to come up money for the HDTVs.

Since HDTV transmissions will be incompatible with the current NTSC transmissions, is it possible and likely that TV accessory manufacturers will come up with an economical convertor box to convert HDTV transmissions into NTSC signals, so that HDTV broadcasts can be viewd by regular NTSC TVs?

Your comments on the topic are appreciated. Please email your response to pmzone@clearlight.com. Thank-you

>
>I have had my DSP 232 for about two weeks and I cannot seem to xmit or

HI George,
I just bought a DSP-232 myself. I have i working in ASCII and BAUDOT just fine using both the audio AFSK output and the FSK (true FSK keying) outputs.

What is weird though is that AEA forgot to put a CW key output on the back of the unit... Morse software works just fine, but you can't use it because you can't get at it.

The received characters are displayed real funny as well (five at a time ??). I also can't stay connected in PACTOR.....

Other than that, a really fine unit..

The statement about non support of the older products is somewhat true and I was remiss for not mentioning it earlier. The last time I spoke with the test equipment repair folks in Schaumburg they told me they would not support the A models. B models are supportable IF you whine at them enough and such. They would definately support C models and of course, the current D models.

If I were buying one, I would buy nothing older than a B model. C and D models are, of course, the preferable choice.

>If making modifications to allow extended rx/tx on amateur radio
>is illegal then why is motorola allowed to sell comm. radios that
>tx in the amatuer bands (146-174) ???
>.

The answer is simple. Radios that are type accepted in the amateur radio service have user selectable frequency capability. That means the user picks the frequency it transmits on.

Radios that are type accepted in the various commercial radio services do not allow the user to pick the frequency, only select from one or more predefined channels that cannot be changed except with means the user does not possess, such as a programming jig or cable, pc based software and adapter cables and stuff like that.

Because commercial radios are not field programmable, there is no problem with allowing them to transmit in the amateur bands because a knowledgeable person must make an effort for those radios to do so. That implies a person has permission (license) to use those frequencies.

I can take an old motrac and throw channel elements in it and it will tune up on the ham bands. The only difference is between having the frequency selected by the channel elements or by a piece of software that runs on a pc. I am glad Motorola has allowed the overlap of band ranges because it allows me, as a user, the flexability to use first rate equipment and not experience the intermod and other problems that others, who run rice powered equipment, constantly complain about.

Totally agree!
You would not believe the number of times I have gotten into heated discussions with people who want to, or have modified their radios to do things they are not supposed to be doing. This all goes back to the god concept that some amateurs have about having a license and being able to do what they want. Others suffer from a case of the cheaps because they want to carry a portable or mobile for amateur use and want to use it as an EMT or other service and don't want to make the investment in a real radio for the application.

The bottom line of this whole arguement is, if you really need a radio for commercial service, someone will buy it for you OR you can save your pennies and go buy a real radio yourself.

There is not a single legitimate arguement for transmitting out of band in another radio service. PERIOD, end of story, close book.

Now I can see the barrage of arguements coming about transverters and health and welfare, etc, yadda, yadda, yadda. Transverters first. What did I just say? I said TRANSMITTING. Using a radio out of band to drive a transverter is NOT transmitting. It is assumed the out of band signal is not for transmission. The resulting transverted signal, on the other hand, IS. So with transverters, there is no problem. Besides, what we are really discussing are the cowboy type amateurs who are really cop wannabees who

have watched way, way too many COPS episodes and go purchase an old state troopers cruiser and fill it up with ham gear to, at first, listen to their local VHF/UHF law enforcement channels. Then things get more interesting as those folks like the feel of the power of being able to key the local sheriff's repeater. They can do something the general population can't and the cool part is, no one, not even the local cops know they are there, and they like that feeling.

Thank God for trunking and securenet. This technology brings a lot of this activity to a screeching halt.

As for health and welfare, the number of high band and UHF users are getting smaller and smaller every day as more cities and states turn to trunking and other technology for management and spectrum effiency. Yes, I am aware of frequencies that are supposed to be monitored for, as an example, statewide use and if you yelled long enough on those channels you might get a law enforcement agency. The problem is, there are too many other methods of summoning help that are instantly available. Going on other services radio system to get help is the LAST resort. When we ask the question of an emergency situation, was an out of band transmission the LAST resort to obtain assistance, the answer, almost invariably, is NO.

I would like to see the blocking of transmission capability above 450.000 and below 420.000 for UHF and below 142.000 and above 150.000 for VHF for the new products introduced into the US market. As much faith as I have in radio amateurs, from what I have seen so far, the problem of out of band transmission will not go away by simply chosing to use equipment properly. The misuse is growing with every new radio introduced and the call for new mods. Every owner of a modified radio thinks he/she is not adding to the problem. Maybe not intentionally but we see now how the internet is being maligned by the media and amateur radio can be seen the same way. (When you see the word media, see a distribution system for information gathered by people who have no idea what they are talking about so they can deliver disinformation to people who are made afraid of those who can do something the general ignorant masses can't. Strange and weird? Only to those who never took the time to see if they might be interested and then to get involved.) It is this type of activity, combined with public disclosure that results in massive fear based legislation that adresses an imaginary problem. Remember the communications decency act? I don't believe it has a chance in hell of making it through the courts, but the FEAR and DISINFORMATION spread about the net gave folks the evangalistic zeal to try to do something to make themselves feel protected. Like I need the government to protect me from the big bad net. Cry me a river. These folks are the ones who are roadkill on the information superhighway and they wrote their congressman to complain. Public knowledge of misuse of amateur radio gives the big corperate boys ammo to attack the amateur radio service to get more paging and trunking system spectrum. We do have an image to uphold!

Magloughlin's Theory: Any stupid idea can be passed into law provided there is enough compelling fear behind it and a profit to be made.

Notice I did not say anything about extended receive. I have nothing against reception of any non encrypted signal. I encourage listening. But I will also mention tightening up receivers is not a bad idea as it would help with a lot of the intermod problems amateurs have in the metro environments we find ourselves living in. The trouble is, no manufacturer of rice powered equipment will spend the money to put a real front end on a radio to be sold to the amateur population. The costs would be prohibitive.

: mount possible?
: Thanks.
:
: -Dan.
:

You will definately want a mobile antenna, not only because of
its better range, but often rubber ducks don't work if you try putting
too much power into them. Which one you want, like everything, depends
on what your doing. A 5/8 has superior gain, but the darn thing's 4 feet
tall (beware of low lying branches!). 1/4 is only 20 inches and in a
city, it's low gain can be an advantage; you get more radiation up and
over the buildings.
Yes, mag mounts are easily available.

I have an htx-202 and am generally pleased. Two suggestions:

Radio Shack puts the htx-202 on sale once or twice a year for under $200;
also there are mail order sites that offer the same rig with same
warrenty at discount. I don't have any numbers or addresses but perhaps
someone who reads this will.

Go ahead and get the extended warrenty. For most items, this is a waste
of money, but with the abuse an HT recieves it's a bargain!

If you have web access, you will be interested in the following site:

Thanks for reading this:

I have a Kenwood TM-241A 2meter rig. I would like to mod it so that I can transmit on local Civil Defense freq (153 mhz) for Races.
Everything that I have found on the mod says to put a 1N914 diode on D209 of the board behind the tone button. The mod worked fine on
TM-231. But on my TM-241, there is a small black chip located where D209 should go. I have tried the diode in several other positions
around there, but none worked.

Does anyone have any ideas? Send any ideas to: usdhicks@cc.memphis.edu

The Icom IC-720A DEFINITELY has a low band antenna input. To listen
below 160 meters, use the separate RCA connector as your antenna input,
not the SO-238 connector. Gets AM broadcast and lower bands just fine
with a long wire.

I am looking for a VERTEX radio. I am on a local fire squad and would love to be able to talk to the dispatcher from my car on the way to a fire. This radio must be portable, 5 watts, programable and a scanning radio. I know that the vertex FTH-7008TD fits these specs, has anyone ever used this radio?

I am a little confused about what type of radio i should buy, the fire frequency is 33.7000. i have been told that is a low band, what is a low band??? Is that in the UHF or VHF line of frequencys??

Is there a big dealer of Two-way radios?

If anyone could help me out it would be great.

Hello,

I am looking for a transistor model 2N3924. It's a NPN RF medium power transistor. I am not looking for equivalent of NTE (it's NTE473), I have had bad experience with this NTE. If you have any other info about this transistor or maybe have it, I am willing to pay for it and for its P&P. Couple of units will be better then only one, but I can manage with only one.

I can't find this specified transistor any where here in Israel!

My e-mail address: 4z9chb@haifa.ampr.org

TIA !

Actually, there doesn't need to be a return path either. This concept of a "loop" is being misapplied and is absolutely wrong.

Current at the output connector of the transmitter will be *forced* to be equal and opposite by the fact that a coaxial cable is attached. Even if the center conductor is disconnected at the antenna, the current within the coax will still be equal and opposite. This is what satisfies Kirchoff in terms of the current supplied by the opposing poles of the transmitter.

It's also what I meant when I said earlier that RF at the output end of the coax is a free agent. It is under no obligation to Kirchoff or any other law to return to the transmitter, to radiate, to be absorbed by earth, etc. It can fail to do all those things and the two poles of the transmitter will still deliver equal and opposite current.

Gary, you're absolutely right about this and I should have been more
careful in my comments. Our limited senses and instrumentation don't
allow direct measurement of voltage, only its effects.

This does not mean that voltage is not a substance, however. I used
the phrase "essential essence" intentionally, as this is the very
first definition of "substance" according to my copy of Webster's.

Also, your reply doesn't respond to my statement that voltage is
attracted to all unlike voltages. Are you disputing this or is it
actually a similar disagreement regarding definitions? I reread your
previous post, but I'm still not sure.

Incidentally, unless I'm missing some of your articles, I haven't seen
a reply to either of my posts discussing the impedance of the
transmitter chassis (one was the article quoting the Antenna
Handbook). The common mode impedance of the chassis is one of the
basic issues behind our disagreement regarding the correct shield
length. Have you changed your position on this?

73,
Jack WB3U

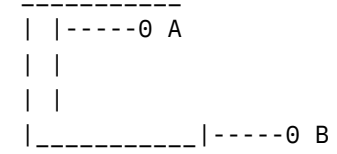
During the discussion of shield length, I haven't seen anything here about the cause and effect when an end-fed wire is driven directly by the transmitter. The mechanism by which this creates RF in the shack is much different than when coax is used. Considering that many operators probably use an artificial ground in order to minimize problems with end-fed antennas, I think this subject deserves a short treatment.

In the case of coax, RF on the chassis of the transmitter is caused by current flowing on the outside of the shield. The transmitter itself remains "balanced" to the extent that the currents flowing on the inside of the coax are forced by the coax itself to be equal and opposite. This means that equal current is being delivered by each pole of the transmitter (one pole is the center conductor, the other the chassis flange of the output connector).

When an end-fed wire is used, that situation changes. Now there is nothing external to the transmitter proper to force the currents to be equal and opposite, so the antenna attempts to draw current from only one pole of the transmitter. That's a physical impossibility though, because both poles are in series inside the transmitter, therefore the current delivered by both poles *must* be the same.

To explain what happens, the influence of an earth ground connection to the transmitter (or capacitance to ground) must be temporarily ignored. Think of the transmitter as a simple, two-pole RF generator, as shown below:



If a center tapped load is connected across this generator, the voltages at A and B will be equal and opposite if measured to the center tap. Likewise, the current that flows through point A will be equal to the current that flows through point B.

Getting back to the real world, one terminal will actually be connected to the chassis of the transmitter (for sake of argument, call it B). Also, even if there is no intentional ground wire, capacitance between the chassis and earth will be sufficient to reference the voltage at B to ground potential. It must be understood that under these conditions, ground is only providing a reference, not a path for the current produced at the output terminals of the

transmitter. Because of this, very little current must flow between the chassis and ground in order to bring the chassis to near-ground potential.

With ground connected, the voltage from A to B is exactly the same as before, measuring from the center tapped load. However, if we measure from ground, the voltage at B will be near zero, while A will now appear to have twice the voltage as before. As explained in my other post "The Transmitter Chassis", this is why the center pin of the output connector is hot, but the chassis isn't.

Now, when we connect a load only to terminal A, two things happen. Current leaving terminal A must return to the other terminal of the transmitter in order to complete the circuit. If there is no return path, current cannot flow. Because B is not connected to the load, there is only one path for the return current - through the capacitance (or ground wire) between the chassis and ground.

Thus, the first thing that occurs is that a current roughly equal to the current at terminal A will flow through the impedance between the chassis and ground, and also through the chassis of the transmitter. The lower the impedance of the ground connection, the more easily current will flow through terminal A. In effect, the ohmic and radiation resistance of the antenna wire attached to terminal A is in series with the impedance of the ground connection at the chassis.

This leads us to the second phenomenon. Because there is now significant current flowing through the impedance between the chassis and ground, the chassis is no longer held at ground potential by that impedance. Instead, a voltag drop occurs, and the voltage of the chassis rises in proportion to the current flowing out of terminal A.

Thus, the transmitter now has current flowing on the chassis and all conductors attached to the chassis, causing everything to radiate. In addition, the voltage on the chassis has risen above ground, perhaps to a level sufficient to burn the operator.

If there's further interest in this topic, the next discussion should probably include a description of why and how the artificial ground remedies these problems.

73,
Jack WB3U

Gary:

I understand that your analogy of the executive toy, but for transfer of power there must be a transfer of charge across a potential difference. Even though one electron may not "flow", the net effect is that one does even if it is made up of little steps of individual electrons.

As I understand it, in the near field of the antenna there is a net charge that flows between the radiating elements (gound plane as well) with its source being the transmitter. The movement of this charge creates the H field and the potential difference creates the E field of the radiation.

The key is that the net charge must be neutralized, return to the source, or that charge will build up on the source, radio. I think that we are saying the same thing, but with a difference perspective.

Jim

Gee, between Jack thinking voltages are attracted (rather than being the potential difference that *does* the attracting), and Tom's use of kilograms as electrical units, I hardly know where to begin. Since I've addressed Jack about the nature of voltage, I think I'll make another attempt at Tom's "electrical mass". Presumably, since you mention charging and discharging, what you're really trying to describe is capacitance.

The Earth can act as one plate of a capacitor, but just as you can't have a naked potential, but rather need two points, it also takes two plates to form a capacitor, and it is the mutually opposed plate areas, and the spacing, that determines how much capacitance you have. If one plate is much larger than the other, the capacitance doesn't change, since only the mutually opposed areas matter (neglecting edge fringing effects). So the fact that the Earth is big (and massive) wouldn't seem to make any difference. (It could make a difference in electro*statics*, acting as a charge reservoir, but not for alternating currents where there is no net flow of charge.)

I have been giving this connection to ground business some thought, however, and thought of one thing that could happen. If Earth is matched to the impedance of the outer of the coax, the coax would look much longer to the RF current waves standing on it, IE it's not a halfwave anymore. Since the Earth is a sheet resistance with dimensions many wavelengths on a side for any sensible frequency we might use, that would remove the open voltage node from the rig end of the coax.

However, for that to happen, the outer has to be impedance matched to Earth, otherwise there's an impedance discontinuity at the junction, and you still get reflection, and a standing current wave on the coax

outer with a maxima at the junction. I don't think typical station Earth connections are actually matched, so I'd treat this case as exceptional rather than the norm.

The impedance of the outer is rather ambiguous anyway since there has to be a reference outside the conductor across which a potential can be expressed in order to calculate an impedance. If, as is the case with single conductors, that reference is a "ground" plane, and that is in fact Earth, you'd be trying to match a two wire "line" to one of its constituent wires at the junction. That sounds theoretically impossible to me.

>
>
>
>Jeremy
>jcon@wdesign.zipnet.net

Any good scanner will pick up those frequencies. They are called
VHF-Low. The "old" scanners that were classified as VHF Low/High
and UHF would receive 30-50MHz (VHF-Low), from 138-174MHz (VHF-High)
and from 420-512MHz (UHF). The main reason for the large gaps is that
the gaps contained either aircraft (108-138MHz) that were transmitted
AM or television channels. Many of the newer scanners will pick
up 30MHz to 1300MHz, excluding the cellular phone frequencies.
Hope this helps.

>shield that is terminated by a finite degree of coupling to earth at
>the transmitter.

You're falling into the trap of implicitly assuming a matched termination for the currents on the outside of the outer conductor. In fact, Earth is extremely unlikely to provide a matched termination to this current, wave reflection will occur, and the behavior of currents and voltages on the halfwave section will be similar to those found if it were operating in isolation, IE the normal antenna current standing wave pattern will exist. Incidentally, that's why a halfwave vertical worked against ground has a very high base impedance, and you have to tap up on it with a shunt feed to match a 50 ohm coax to it.

How do you "open up" a single wire?

>Broadcast towers (even dipoles and other antennas) are commonly treated as
>transmission lines with a single conductor impedance (Zo). If a single
>wire **can't** act like a transmisssion line, then how do long wires
>function?

Not as transmission lines in the sense you seem to mean. :-)

An antenna works by establishing a standing current wave pattern
between its ends because they are *not* terminated in the characteristic
impedance of the line. Charge is conserved because charge merely oscilates
back and forth on the wire under the influence of the varying polarity
driving potential. Thus the charges are continously accelerated (and
decelerated) and hence generate EM radiation. Energy is conserved, but
is changed in form. An ideal antenna has "infinite loss" of charge motion
energy because it is all changed to a like amount of EM radiation energy.

In a transmission line, even one with standing waves, radiation doesn't
occur because the differential current flows cause the H fields to cancel.
Charge must be conserved by closure of the loop, and energy must be
conserved too because its form can't change. Thus an ideal transmission
line has zero "loss".

Practical circuits are always a mixture of both forms due to various
stray couplings and the finite resistance (heat loss) of the conductors.
So you can *partially* use transmission line theory on antennas and
partially use antenna theory on transmission lines. But neither offers
a complete solution.

>The truth is, the conductor is both a radiator AND a transmission line.

Yes, and you can't just apply one form of theory as you and Jack and I
have been doing. In the interest of simplicity, we can treat only the
dominant action and ignore the other as peripherial. I say antenna
behavior dominates because of the lack of differential balance while
you and Jack say transmission line behavior dominates, but you've been
unable to close the loop to show that is so.

>
>Are you actually saying that I can't excite a single conductor with RF,
>and have current and voltage appear for many wavelengths along that
>conductor unless there is a "return path" from the far end?

Yes, that's exactly what I'm saying. You must have another point
of reference for the potential to express itself across, and then
you don't have a single wire system anymore. Your reference wire
or plane becomes the other half of the transmission line and closes
the loop. You can't have a naked potential, that's meaningless
by definition.

>>It is not behaving
>>as a transmission line. It is behaving as an excited resonant 1/2-wave
>>antenna structure. *The point where the excitation is applied does
>>not change the standing wave pattern on the radiator.* It must have
>>voltage maxima at its ends.
>
>Let me see if I understand this statement. Are you saying, if I ground the
>far end of a half wave antenna, the current maximum STILL occurs in the
>middle instead of the end?

Yes. A classic example is a shunt fed grounded base halfwave vertical.
You have to shunt feed it because the "grounded" end is a very high
impedance point, just as the top end is. Ground is acting as a current
mirror, just as it does for a grounded base quarterwave, but in this
case the mirror is reflecting the end of another halfwave antenna
and the "ground" point is a very high impedance. Hence you have to
tap up on it with a shunt feed to find a higher current lower voltage
point that corresponds to the impedance of your feedline. The current
maximum is still in the center.

Again, not bad for the 1950s, but we expect better today.

>>Also some of the tubes are getting harder
>> to find and are becoming expensive.
>
>Nothing in the Viking II is rare, hard to find, or expensive

Most of the tubes in the Viking II are out of production, so all
that is left is existing stock, which is dwindling, and some of
that old stock has deteriorated on the shelf. So the tubes are
getting harder to find, and becoming more expensive, than they
were in the 1950s. And some other parts of the rig are pure
unobtainium.

>today's beginners aren't capable of doing much but opening the box and plugging the
>plastic radio-thingy found there-in into the wall? Is more than one knob too many?

I wouldn't call a VIking II a beginner rig, not in 1955, and not today.
In 1955 beginners started with a *new* Challenger, and a *new* National
or Hallicrafters receiver. Today beginners have much better choices than
50 year old equipment. Receivers are *much* improved (and built in), and
transmitters occupy a much smaller footprint and use contemporary parts.
It has nothing to do with the skill level of the beginner, then or now.
Rather it has to do with the level of performance, maintenance, and
operator flexibility offered by 50 year old equipment compared to
equipment of modern manufacture. In particular, 50 years ago beginners
weren't faced with scrounging 50 year old parts to repair 50 year old
equipment. Back then the Viking II was *new*. It's 50 years old today,
and the maintenance requirement is *very* different than it was when
it was new. Anyone who has had to restore one of these should know
what I mean. If you can't pick the bones of another carcass for some
of the parts, you're just plain out of luck, and lots of those carcasses
have long been landfill.

In my experience, the matching network of tube-type finals
such as with a linear amp are adequate for up to a 3:1
SWR, which is actually about all many tuners are capable
of. Paying big bucks for an external tuner is pretty much a
waste, IMHO.

Now with solid state finals, another story...

Make sure the antenna can handle the power as well..

I'm not afraid to work on a FT1000D, bring one over and I'll heat up
the soldering station. :-)

Really, this reminds me of the people who are afraid to drill a hole
in their car. You own it, you can do what you please with it. At least
if you *fail* to repair a FT1000D, you've got Yaesu factory support to
fall back on. If you fail to repair a homebrew rig, you're on your own.
And framkly, one is about as likely as the other. You have to know
pretty much the same things, and have pretty much the same skills.
One nice thing about factory equipment over homebrew is that you have
an assurance that it *once worked*, so you don't have to worry that
the problem is a design fault or improper construction that's keeping
it off the air.

Other than (grrrr) intermittants, I find modern factory built equipment
a lot easier to troubleshoot than a super regen receiver with its finicky
feedback and quench and demodulation all multiplexed on one circuit.
Modern rigs are generally modular, one function per circuit, stable, no
finicky adjustments, and very straight forward to troubleshoot and repair.
A stage either works or it doesn't in most cases, a part has either failed
or it hasn't. Plain old binary fault tree analysis quickly gives you the
bad part, and you just replace it.

>braid is so flimsy that very little of it comes in contact with the connector.

You must have used some of the very first run of 9913. Belden increased
the braid coverage a few months after it was released from 63% to 97%,
and now there is plenty of braid for a proper connector to grasp. The
best 9913 N connectors are made by Kings. These hold so well that I
wouldn't worry about swinging my weight against one (except that the
cable would stretch enough to change its impedance if I did). They are
of the preferred gas tight crimp design of course, the old Amphenol
screw together types are a horror, even on RG-213. The center conductor
of 9913 is 9.5 gauge while the center of RG-8 is 10 gauge. I haven't found
that 0.5 gauge difference to be a problem with PL-259 connectors, but you
do have to be careful to get the right N or BNC connector for 9913. (I
have reamed the center pins of RG-8 N connectors in an emergency, just
use a small number drill in a pin vise).

Like any coaxial cable terminated in an unconditioned space, you have to
have a gas tight seal at the connectors or you'll eventually get water
inside. 9913 has void space that allows more water to accumulate, but
that doesn't really matter. Once water wicks into the braid, corrosion
starts and any flexible coax will be quickly ruined. 9913 really isn't
worse in this regard.

I consider 9913 a good low loss semi-flexible cable that's sufficient
for uses where the cost of hardline isn't justified. If you intend to
leave the cable up a *long* time (more than 8 years) then hardline is
the cable of choice if installed with its (expensive) gas tight connectors.
But for cable installations where you'll be changing it in a couple of
years, 9913 is fine.

Uh.. Uh.. Interesting. Point # 1 is that supposed law mentioned above would outlaw all of the cellular phones with a test mode (ala built-in cellular scanning on a channel by channel basis). Point # 2 is supposed law would also outlaw TVs with a tunable UHF non-cable TV channel selector as the high end channels can monitor cellular. Point # 3 is that most scanners in the U.S. can be converted to receive cellular by replacing the CPU with an international version from the UK (Javiation for example) since as a raw material CPUs and such are exempt for such laws. Simple task to upgrade it. Point # 4 is that I do not know anyone personally who this law has stopped from listening to cellular or cordless- as my friends and I do it all the time. Point # 5 the only folks this law applies to is law enforcement, as it prevents them from gathering evidence from a cellular or cordless phone conversation without a court order, where it was possible to do so before without.

True it is harder to purchase ready to receive equipment off the shelf, but not impossible to do so. It is more expensive having to import them, which is legal "in small quantities for personal use", only commercial importation was made illegal. As a non-FCC type accepted device, it can not be determined by US customs as to if it is ok or not ok, therefore, only commercial sales was restricted by the law -- which hurts the U.S. dealers in the long run, due to less sales since anyone who knows what they are doing will order from overseas instead.

Several years ago Motorola did sell a 2M FM transceiver. It didn't stay on the market very long.
It would be interesting if they were attempting to market ham products again.

The return path is not through the shield, but on its surface. The shield has two surfaces, inner and outer, and entirely different currents can flow on each surface. We'd like all the return current to flow on the inner surface, where its field cancels that from the current on the center conductor. Current flowing on the outer surface will radiate, just like current flowing on any other wire.

I've seen plenty of electrostatic voltmeters which purport to be able to measure voltage without the presence of current. And my hair is a pretty good qualitative instrument for detecting electric fields on a dry day.

>any help would be appreciated

SAMS has Photofact folders for all of these radios. As others
have noted, you shouldn't need to touch any of the adjustments
in these radios. They were aligned at the factory using better
test equipment than you likely have and shouldn't ever need
readjustment, even after repairs (unless the repair consisted
of replacing one of these adjustable parts).

There is a book out on converting some of these radios to
10 meter operation, there's a little ad in most issues of
QST. In particular, the Midland chassis is rather easy to
convert. Of course these are, I think, old AM rigs and not
of much use on 10 meters. If you had one of the 40-ch SSB
Midlands, however, it can be made into a good 10 meter rig.
I have one that I converted some years ago when the sunspots
were better.

No, Jim. In an *AC* circuit there is no net charge flow. All
charges merely oscillate back and forth around their original
positions in step with the changes in potential. Charge is
fully conserved in an AC circuit. Now a DC circuit is different,
and there is a net charge transport around the circuit. Don't
try to use DC circuit analysis for AC circuits.

Gee, Gary, have you been taking an e&m class or something?? Often I find things to disagree with you on, but this seems pretty solid to me. Jack, I think if you look up "voltage" or "electrical potential" in a good technical dictionary, you will find very good agreement with what Gary says in these posts. I've always enjoyed a comment Ronold King makes in the early pages of his section on antennas in "Transmission Lines, Antennas and Wave Guides." It's something to the effect that one way of looking at radiation from an antenna, received by another distant antenna, is that the electromagnetic wave is simply a mathematical convenience used to describe the observed motion of charges in the remote antenna in response to motion of charges in the "radiating" antenna. The only way you have of knowing that a source is radiating is to measure the effects at a distant point; there is no _direct_ way to measure the "field", just as Gary has noted about voltage (electrical field) above. Some very bright folk seem to be happy to think of the field as just a mathematical abstraction, not a real quantity.

This reminds me of an instrument called a "field mill" which can measure an electrical field with no direct connection to conductors. But I believe even it is probing the field by observing the motion of electrons in that field. You can do an experiment looking at an electrical field if you use an op amp with an extremely low input bias current as a non-inverting buffer. If you leave the (+) input unterminated and very carefully guarded, you can put a little probe on it and move it around in a field and use it to measure the voltage. You need an op amp whose input bias current is down in the 10^-15 amp region to do this well, but it's an interesting experiment. But even here, you are moving electrons in the conductor attached to the op amp (+) input, in response to the field the probe is in. So, you have extracted some tiny amount of energy from the

field to measure it.

(Gary Coffman) writes:
>
>Gee, between Jack thinking voltages are attracted (rather than being
>the potential difference that *does* the attracting), and Tom's use
>of kilograms as electrical units, I hardly know where to begin.

I never said kilograms Gary. I was trying to describe the effect in terms
that would let you get a "feel" for it.

>I've addressed Jack about the nature of voltage, I think I'll make
another
>attempt at Tom's "electrical mass". Presumably, since you mention
charging
>and discharging, what you're really trying to describe is capacitance.

Sort of, except with series inductance it may not appear as a capacitor.
It can become purely resistive at some frequencies, inductive at others,
and combinations of all three. It is an impedance.

>I have been giving this connection to ground business some thought,
>however, and thought of one thing that could happen. If Earth is matched
>to the impedance of the outer of the coax, the coax would look much
longer
>to the RF current waves standing on it, IE it's not a halfwave anymore.

Ther's no reason to be unduly concerned with matching the impedance. The
common mode load can modify the impedance without matching it!

According to your view, any half wave conductor has a low impedance in the
center. If I connect the far end of a half wave conductor to a low
impedance (a large electrical mass) at the frequency wher the conductor is
a half wave long, you are saying that the current maxima remains in the
center.

Isn't that what you said and believe?

If so why, when I make a half wave dipole 1 wl long by adding a 1/4 wl to
each end does the current maxima shift out of the center of the half wave
section? If I end feed a 1/2 wl long wire and add a low impedance to the
far end does the feedpoint a low impedance?

The answer Gary is that 1/4 lines invert the impedance, and half waves
repeat it. So if the coax is connected to the chassis of the rig, and the
common mode length is 1/2 wl, the far end is ALSO a low impedance. The low
impedance encourages common mode currents to flow from the antenna

termination of the feedline.

Antennas do this, feedlines do this. An antenna is a leaky feedline as well as a radiator, and a leaky feedline is a radiator as well as a feedline. The rules all interchange.

>>transmission lines with a single conductor impedance (Zo). If a single
>>wire **can't** act like a transmisssion line, then how do long wires
>>function?
>
>Not as transmission lines in the sense you seem to mean. :-)

Absolutely in the sense I mean. They couple power to the far ends, the end impedance iss transformed at a rate determined by the Zo of the wire and the radiation effects. It acts as both a transmission line and a radiator.

>An antenna works by establishing a standing current wave pattern
>between its ends because they are *not* terminated in the characteristic
>impedance of the line.

Not true at all. An antenna acts like an antenna because charges accelerate without equal and opposite acceleration at the same point in space. A perfectly terminated long wire with NO standing waves radiates quite well. Are we now to believe perfectly terminated Rhombics and Beverage antennas can't radiate?

>Practical circuits are always a mixture of both forms due to various
>stray couplings and the finite resistance (heat loss) of the conductors.
>So you can *partially* use transmission line theory on antennas and
>partially use antenna theory on transmission lines. But neither offers
>a complete solution.

That's correct. That's EXACTLY what I've been saying. Specificially with the addition of common mode currents from improper load potentials at each end termination with respect to the other end.

As I said..
>>The truth is, the conductor is both a radiator AND a transmission line.

>Yes, and you can't just apply one form of theory as you and Jack and I
>have been doing. In the interest of simplicity, we can treat only the
>*dominant* action and ignore the other as peripherial. I say antenna
>behavior dominates because of the lack of differential balance while
>you and Jack say transmission line behavior dominates, but you've been

>unable to close the loop to show that is so.

I never said that at all Gary. Re-read CAREFULLY what I said. Let me repeat it AGAIN.

>>The truth is, the conductor is both a radiator AND a transmission line.

>You must have another point
>of reference for the potential to express itself across, and then
>you don't have a single wire system anymore. Your reference wire
>or plane becomes the other half of the transmission line and closes
>the loop. You can't have a naked potential, that's meaningless
>by definition.

We do have two points Gary. One point is the potential at the antenna terminals, the other is the transmitter chassis! Those are the two points. We can also have a difference along a small length of conductor.

>>Let me see if I understand this statement. Are you saying, if I ground the
>>far end of a half wave antenna, the current maximum STILL occurs in the
>>middle instead of the end?
>Yes.

That is incorrect.

>A classic example is a shunt fed grounded base halfwave vertical.
>You have to shunt feed it because the "grounded" end is a very high
>impedance point, just as the top end is.

No, the grounded end is NOT a high impedance point. The highest impedance point is the top.

> Ground is acting as a current
>mirror, just as it does for a grounded base quarterwave, but in this
>case the mirror is reflecting the end of another halfwave antenna
>and the "ground" point is a very high impedance.

You have confused a tool used to calculate pattern with something that actually occurs. The "ground image" is useful only for calculating pattern. It really isn't "there" at the base of the antenna, or in the soil below the antenna. A perfect radial system is zero ohms, a flawed system is only a few ohms. Connecting the base of any antenna directly to the ground system results in a very low impedance at the base.

>Hence you have to
>tap up on it with a shunt feed to find a higher current lower voltage
>point that corresponds to the impedance of your feedline. The current
>maximum is still in the center.

In this example there are only two true statements we can make. One is a current minimum is indeed at the very top. The other is the base of the antenna is a very low impedance.

If the shunt feed wire did not decouple current from the base of the tower by mutual coupling effects, a current maxima would also occur at the bottom. Anyone with Elnec can see this effect. Only by putting the source near the base of the tower is series with the tower is the effect you describe true. But now we have a conventional series fed tower.

I just got a 736-R in January. No, it hasn't been fixed. Fortunately,
this should only be an issue on the terrestrial portion of the band.
There's a very strong local beacon around 432.250 that I can hear for a
couple of megahertz (!) in either direction with an omni antenna. But I
can hear FO-20 fine (no pumping) on the same omni antenna and no preamp
while the beacon is going. And FO-20 is very faint on an omni, so I
suspect I wouldn't hear it at all if there was any desense.

Hi Tom, Peter and others,

This might explain some things I've been noticing with my 736R also. I'm going to search for mods that might cover this problem. I intend to contact Yaesu to see if they might have some pointers on do-it-yourself mods. I don't have much hope on either of these, so I'd be willing to work with some of you folks on attempting to come up with some modifications ourselves. I don't think I have enough technical expertise to go it alone, but am able to work on it as a team. I'm doing this as I use the radio mostly for terrestrial SSB work right now, and would like to clean it up.

Tom, does the article give any more specific information as to the cause of the problem and/or remedies? I haven't been able to locate a May 90 QST.

Interesting evaluation. I used a Belden 9913 equivilent sold by Pasternak
under their name for a variety of things, and have been very pleased with
it. I bought a 500' roll for $182 on sale about 2 years ago. I am curious
what connectors you are refering to as being poor choices with this cable.
As all my applications have been VHF, I've been using silver/teflon PL259
connectors. These go together very nicely. Will be putting up some VHF/UHF
antennas on the house this spring and expect to use this cable for it. Some
of these antenns will be rotatable beams, so pigtails of RG213 are planned
for the flexibility concern.

Sir,

It's still available. The IBM/DOS Broadcasting Radio Station Database Program for Longwave, Mediumwave, and Shortwave. Over 4,000 records included already. The program is completely read and write. Records can be added or changed. Sorts in many different formats both on your screen and printing.

If you would like a copy of the program, send your request to "chuck@flinet.com". Please include your MAILING ADDRESS. For example, your street number, city, state and zipcode. Also include your Email address.

The program will be sent to you via Email probably within 24 hours if not sooner. If you request the program and haven't received it in that period, check back with me..

Remember to send your address. Requests without a mail address will no longer be acknowledge to save time on the internet. In the past, requests without an address were reminded with a message. Usually, the reminder went unanswered anyway. If it was, the reply was sometimes very rude.

This program is free! Everything works. It has many features and they all work, not like shareware where some of the features work and others don't.

You address will be kept confidential. I will be sending you a first class letter later explaining another full featured Database program available. It's very big!

>happen with 1500. :-)

Rich,

I believe those might have been JUST reports and that's it. I've
never heard of what you're saying. Now, I have heard of people
blowing traps in their R-7s by attempting to load them on 80 meters.
Won't work, wasn't designed for that.

If someone did happen to get an antenna with a defective trap,
however, Cushcraft is usually pretty good about replacing it.

just my $.02

> =====
Point #1: It's not a "supposed law", it's a real law. It's called the ECPA.
And, no, it doesn't outlaw anything except certain scanners. The description
of the banned equipment is found in CFR 47, sec 15.21. Any good library will
have this here in the US, so you can look it up, and know what you are
talking about.

Point #2 is covered under Point #1.

Point #3: The law does not make such modifications illegal, even thought the
opportunity to do so was clearly present. The language (see reference above)
is, "...must be incapable of operating (tuning), or readily being altered by
the user to operate, within the frequency bands" for cellular phones.

Point #4 means nothing. People still rob banks, that certainly doesn't mean
we should repeal the laws making that illegal.

Point #5 is just plain wrong. Nowhere is this law aimed only at law enforcement.
To say that is only wishful thinking on your part.

> True it is harder to purchase ready to receive equipment off the shelf,
> but not impossible to do so. It is more expensive having to import them,
> which is legal "in small quantities for personal use", only commercial

> dealers in the long run, due to less sales since anyone who knows what they
> are doing will order from overseas instead.

Much of this is true, however, the rules do *not* make a distinction between
commercial and personal importation.
At this time, the Customs people are not enforcing the ban on importation
for private use/individuals, but this can change at any time, at the whim of
Customs.
A non-FCC type-accepted device can be impounded at the border by Customs,
as that's part of their job. I have no idea where you came up with this.

>Is there an improvement mod for the IC735 noise blanker? If I turn the
>blanker up high enough to reduce the noise, the audio becomes
>distorted.

That's a surprise? When a blanker blanks, it kills the desired signal
for the duration of the noise pulse as well as the noise pulse itself.
Of course that's going to generate distortion, that's inherent in
the process. The hope is that the resulting distortion is less annoying
than the noise that is removed. I believe that the time constants used
in the IC-735 blanker are as close to optimum as you can reasonably
expect in a radio of its type. You can play with the time constants,
but I don't think you can substantially improve upon them. The slice
level setting is absolutely critical for best performance on different
types of impulse noise and signals, so you need to set that carefully
on a case by case basis. If the impulses are wide or very frequent,
then you may do better leaving the blanker off because too much of
the desired signal will also be lost and the distortion will be severe.
There's no good way to handle this problem using a blanker. A noise peak
clipper may be better in these cases, but the real answer is to eliminate
the noise at the source.

I hope this doesn't sound like I'm trying to teach you to suck eggs,
you may already know all of this and still hope to improve the blanker
in the IC-735. I've had my IC-735 for 7 years and I've tried modifying
the noise blanker time constants for better operation. I wound up back
at the factory values. I don't think you can get it to work much better.
I think that if the blanker can't handle the impulses without unacceptable
distortion, you're going to have to do something else to deal with the
noise (like using an ANC-1 noise canceller).

I too bought the DX-70. If you read the QST reviews of DX-70 and IC-706, you will see that the DX-70 has a better receiver for IM and its built in filters. I suspect you will find fewer options available for the DX-70 however. Drawbacks: only 10w on 6m, and no 2m. As far as I am concerned from listening to people who own the IC-706, the 2m part of the radio is so poor that it might as well not be there. I want to listen to 2m, and hf at the same time, thus I need 2 radios anyway. I think Icom should have spent their effort on improving the hf side of the box, and leaving 2m out. Then the IC-706 WOULD HAVE been the obvious choice. What do you want, all in 1 box, then buy the IC-706, or, a really good hf radio to compliment your existing equipment in the mobile, then buy the DX-70 (and save a bunch of $).

$479?!, why don't you shop around and buy a nice 2 meter mobile for $250-300? I take it you are looking at the price listed in the catalog and haven't called and asked for the 'actual' price yet. I don't know why the bone headed places don't list the real price to begin with. It would make deciding what to buy a lot easier. I think HRO finally got real prices listed on their WEB page.

First, what was the purpose of the Artificial Ground? What were your
performance objectives?

Second, how is your inverted V being fed and how is it tuned on 10-40
meters? Does it have traps? Are you using a balun?

>My feed line to the antenna is also 30' long. The antenna is mounted

Is one leg of the V actually longer than the other, or did you mean
something else?

>Things seem to work fine and I'm able to make contact with almost
>anyone I hear. But like others I want to be able to do the best I can
>with what I have. Does anyone have any suggestions on what I can do
>better, if indeed I need to.

You may not need to. The trick is to minimize the losses in the feed
system. Loss can be resistive or it may be the result of radiation
from the feedline. The latter is only a true loss however if the
operator is certain that energy radiated from the feedline is
unusable. Depending on many factors, it might occasionally be of
benefit at the receiving end, although it's certainly a pain to deal
with at the transmitter.

Maybe you could describe the antenna system in a little more detail?

>attracted to all unlike voltages. Are you disputing this or is it
>actually a similar disagreement regarding definitions? I reread your
>previous post, but I'm still not sure.

I am disputing that. Voltage is a *potential difference*, like a
gravitational potential difference, it is an artifact of *position*.
In the case of a gravitational potential difference, the position
of two points on a curved space-time establishes the gravitational
potential difference between the points. Move the reference points,
and the gravitational potential difference between them changes, but
nothing about the curvature of space-time has changed. It's the same
with voltage. It is an artifact of the location of two points in an
electric field gradient, change the location of the two points, and
the voltage changes, but the electric field gradient has not changed

or moved.

Just as the only substance with gravity is mass, which causes the curvature of space-time, the only substance with electricity is charge, which causes the electric field gradient. Everything else is an artifact of position and has no substance. Thus voltages cannot be attracted to other voltages since voltages have no independent existance, rather they express a relationship between points which can be arbitrarily moved which are located in an electric field gradient established by the presence of charge.

Charges can attract (or repel) other charges, IE currents can flow, but voltages cannot flow, IE they cannot attract or repel each other because there is nothing about a voltage to be attracted or repelled. They only express a relationship between two arbitrarily selected positions in an electric field gradient.

Voltage is an artifact of charges and positions, but charge is not an artifact of voltage or position. This is the critical point to remember. Charge has objective reality, voltage is just an effect.

I tried to get to this mathematically in another post, showing that voltage must be associated with a distance between two points, and that those points can be independently and arbitrarily chosen without regard to charge. Now to bring this back to the topic at hand, lets see what that implies for impedance. Impedance is defined as Z=E/I. Now to get a value for E, we must select two points between which to measure. Not so obvious perhaps, those two points must lie in a common electric field gradient in order to have meaning to the circuit. That gradient is determined by charge flow, I, in this case, and a fundamental law of physics is that charge must be conserved, IE we cannot create arbitrary amounts on demand at some arbitrary location, or destroy abritrary amounts on demand at another location. Therefore the charge path must be closed in some manner, IE a conservative circuit, or we are dealing with an electrostatic phenomena and not electrodynamics.

So voltage measurements made referenced to a third party not involved in that closure have no meaning in regard to the dynamic impedance in the circuit. And finally, measurements referenced to Earth have no meaning with regard to impedances in the circuit under discussion since it does not participate in the conservation of charge in the circuit, IE it is not in the return path, and the electric field gradient, if any, it may offer has no direct relationship to the charge, and hence current, in the circuit.

Gary

But of course they can't. They need a flow of charge into the instrument
to create the displacement that they measure. Because they are dealing
with electrostatics, the flow need not be continous, but it has to occur
nonetheless, and of course a flow of charge *is* current.

>And my hair is a pretty
>good qualitative instrument for detecting electric fields on a dry day.

Yes, but electric fields by themselves are not voltage, which is a difference
across a gradient. It is the charges on your hair being displaced by the
electric field gradient, IE a momentary current flow, that is actually
causing the hair to stand.

We cannot directly measure a potential difference, we can only infer
it indirectly by the charge displacements it causes.

>No, the grounded end is NOT a high impedance point. The highest impedance
>point is the top.

But wait, it's a halfwave, and you've been telling me that the impedance
of a halfwave repeats at each end. So if you say it is high at the top,
it has to be high at the bottom too. Can't have it both ways.

Now lets take you at your word here and assume a halfwave grounded
at the bottom does *not* then present a low impedance at the top.
In that case I have just won the debate since I've been saying that
the high impedance at the top is why the halfwave line won't accept
currents from the low source impedance of the feed.

Either I'm right or I'm right. I love it. :-) :-)

Frankly, I believe that the bottom is also a high impedance from
the only point of view that matters here, that of the currents on
the conductor. Earth in and of itself has no particular impedance,
high or low. It assumes whatever impedance is necessary to satisfy
Z=E/I for the values of E and I measured across and along points
in the mesh.

The whole fallacy of your and Jack's argument has been this insistence
on an absolute impedance for ground that is low. Impedances, like voltages,
are only relative to the two points across which they are measured. There
aren't two points with Earth in between in this case, so we can say nothing
about the impedance of Earth from the POV of this circuit.

>current that Jim asked about.

Perhaps it would be useful to discuss precisely what we mean when
we talk about a "flow of current" in relation to AC. What exactly
is flowing if it is not charge? But lets defer that for now.

>It is much easier to understand what's happening if it's remembered
>that the transmitter has two RF output terminals (poles). The only
>"loop" that must exist in order for current to flow is the current
>path internal to the transmitter and through the load. To satisfy
>Kirchoff, the current flow through all internal points and through the
>two output terminals must be the same.

Yes, I've been saying that long and loud since the start. The topology
is conservative. Kirchhoff's Law can not be violated.

>What you've missed is that current drawn from those two poles is
>forced to be equal and opposite by the inherent nature of the fields
>inside the coax. Therefore, regardless of the load at the far end of
>the coax, the load seen by the transmitter itself is *always* balanced
>at both poles. Nothing is attempting to draw more current from one
>pole than the other, therefore there is no need for any "return"
>current in order to balance the transmitter. **This condition is
>satisfied whenever coax is attached to the transmitter.**

Ok, so if we believe this, there can be no current flowing down
the outside of the coax because all the current that came up to
the load on the inner had to go back down on the inside of the
outer, and vice versa on the other alternation, because you say
coax *forces* this condition. So now you're left with trying to
explain the source of the current that we know *is* flowing on
the outside of the outer of the coax. Where's the generator for
that current if it isn't the transmitter?

>Please stop this nonsense about some sort of external loop that must
>be completed. It is an instinctual concept that does not exist in a
>coaxially-fed system.

Try again. Your paragraph 1 above states correctly that all current leaving the transmitter must return to the transmitter, Kirchhoff's Law must be obeyed. Your paragraph 2 then states that coax *forces* the currents on the inner and the inside of the outer to be in balance, but that leaves I + (-I) = 0 current remaining to flow down the outside of the coax outer. So you now have to invent another current source in order to explain the current that *is* flowing down the outside of the outer, or contend that there *isn't* any current on the outside of the outer and that this whole thread has been built on a faulty premise that cannot happen and that there can be no such thing as a hot shack when we use coaxial feedline.

If you try to say currents spring into existence without a generator, then you've invented perpetual motion and we can sell that "free" current flowing down the outside of the coax to the power company and retire rich, IE you'd be claiming 1+1=3.

[Note: for those not following closely, I know that's not true, it is merely an implication of Jack's version of how things work. As a hint for those playing at home, an understanding of what we really mean by AC "current flow" is a key to understanding what's really going on.]

Hi Steve,

The 730 was a good low end radio. It is ham band only. Works very well on SSB. For CW there isn't enough selectivity and you will want a secondary audio filter.

Price for a used one in good shape should be about $450.

Bill

In case no one has said what I'm about to say:

I agree - first check your own homeowner's AND auto insurance. I have had the ARRL insurance for the purpose of insuring my mobile rig, but now State Farm WILL cover 2-way radios that are BOLTED DOWN (as opposed to sitting on a seat, unbracketed). Since I have ZERO deductible on my Comprehensive for car insurance, I will recover full replacement costs should the radio be stolen. If you have a deductible, see how much it would cost you to either lower the deductible or reduce it to zero; THEN compare that to the cost of ARRL insurance WITH their $50 deductible. And remember, too, the ARRL insurance (for some reason) requires you to list ALL your ham radio equipment, even if you DON'T want to insure it. The more you list, the more you pay.

The ONLY good thing I find about the ARRL insurance is that it is basically (as I understand/recall) all-risk. Should a piece of equipment be damaged by a cause that State Farm doesn't "recognize", then you are screwed.

Doug,

I built the Ramsey kit for 220MHz. I had a problem with noise (jitter)
in the synthesizer, and have sent Ramsey a letter about it, sereval weeks
ago, with no response. (I had managed to borrow an ~$10,000 "station
monitor" to analyze it with, and sent Ramsey those results.)

The layout for the Ramsey kit leaves a _LOT_ to be desired. They are
physically very fragile, and have the problem of using a diode matrix
for programming.

I also have a problem with mine in that in mobile service, it won't even
"kerchunk" the repeater from about a mile and a half with the engine running,
while with the engine off it'll bring up the same repeater solid from 25
miles away (same antenna, too).

The only service I can advise for the Ramsey is possibly for packet,
though I have not tried it myself.

If the 2M radio from Ramsey is of the same level as their 1.25M radio,
you'd be a lot better off sprining the extra $30 or so and getting a
Radio Shack HTX-202, and the cord for the cigar lighter (use the drycell
pack empty in this configuration if you want the ignition switch to turn
off the radio).

73,
Clark

gary@ke4zv.atl.ga.us (Gary Coffman) writes:

>I have been giving this connection to ground business some thought,
>however, and thought of one thing that could happen. If Earth is
>matched to the impedance of the outer of the coax, the coax would
>look much longer to the RF current waves standing on it, IE it's not
>a halfwave anymore.

Gary, I am very glad that you are reconsidering the effects of the earth ground at the transmitter. This is critical to understanding these issues and it is one of the mechanisms that is almost totally ignored in ARRL literature (except for what I quoted). Honostly, it has taken me years of RFI and RF burns to fully understand what was wrong with my systems. I finally had to abandon all the complicated theories and start at the beginning. When I was done, it turned out to be so simple that I wanted to strangle the nearest engineer (and more than a few editors). ;)

Getting back to your statement, "... the coax would look much longer to the RF current waves standing on it, IE it's not a halfwave anymore.", you're correct. However, this primarily causes the impedance at the transmitter to rise above ground potential, compared to being directly grounded to earth. *In practice*, the 1/2 wave shield will still reflect the impedance at the transmitter back to the source due to the way in which the waves combine.

>Since the Earth is a sheet resistance with dimensions many
>wavelengths on a side for any sensible frequency we might use, that
>would remove the open voltage node from the rig end of the coax.

For practical purposes, it is a resistance with an *infinite* length. RF current flowing through earth is attenuated to an infinitesimally small value long before the "end" of the conductor is reached.

You're right - there is no voltage node at the transmitter (unless the length of the conductors and capacitance between the chassis and earth combine to form the equivalent of a 1/4 wave line).

>However, for that to happen, the outer has to be impedance matched
>to Earth, otherwise there's an impedance discontinuity at the
>junction, and you still get reflection, and a standing current wave
>on the coax outer with a maxima at the junction. I don't think
>typical station Earth connections are actually matched, so I'd treat
>this case as exceptional rather than the norm.

Right again, there will almost always be some reflection. That's OK though. The transmitter still won't be a high impedance point in absolute terms.

> The impedance of the outer is rather ambiguous anyway since there
> has to be a reference outside the conductor across which a potential
> can be expressed in order to calculate an impedance.

The reference is earth. Both the transmitter and our bodies are referenced to this potential by (at least) capacitance. When someone touches a transmitter chassis and receives a burn, it is because the transmitter is no longer referenced to earth.

Also, you only need a reference at *one* end of a wire to determine its characteristic (surge) impedance. If that reference is ground, the impedance of a horizontal wire can be calculated on the basis of the wire's diameter and height above ground. In real terms, this is usually between approximately 500 and 1,000 ohms. Even if the wire is vertical, it still has a specific surge impedance referenced to ground.

>If, as is the case with single conductors, that reference is a
>"ground" plane, and that is in fact Earth, you'd be trying to match a
>two wire "line" to one of its constituent wires at the junction. That
>sounds theoretically impossible to me.

Yes, it's extremely unlikely that a match would be achieved in a random installation. However, not only don't we need a match, we don't want it. As long as the terminating impedance is *less* than the surge impedance of the line, the 1/2 wave line will exhibit *current maximas* at the ends. The worse the mismatch, in terms of the termination being lower than the surge impedance, the higher these current maximas will be. This is why a 1/2 wave line won't isolate antenna current from the transmitter.

Gary, I think you're much closer than you realize to being in agreement on this issue. Unless you take serious issue with my replies, we already have a partial consensus.

73,
Jack WB3U

I would be very surprised if they would. Your best bet is to sell it
at a local hamfest or put an ad in the paper. The current sale price
for a 212 is $269.99, so I would price yours a little lower (maybe
249.99 if you have box and manual).

Wow, I never thought that my original post would create so much information... What I'm really trying to get to is, I have a Kenwood TS-450SAT currently connected to a multiband inverted V antenna tuned for 20, 15, 20, and 40 meters. My station is located in a room on the second floor of my home. My space is limited for the antenna and want to have the most efficient station for the space and location I have. I haven't had any problem with RF in the shack even befor I added a ground. Since my first post I have added a ground stake and ran a 12 gauge wire from the ground post of the radio to the ground stake. It's 30' long. Now everything I've read says you need to have a ground wire as short as possible in order for it to work. In my case 30' is as short as I can go. This is why I was looking into the Artificial Gound. But it really didn't work as I expected it to. My feed line to the antenna is also 30' long. The antenna is mounted at the eve of the house and goes down at a 45 degree angle to the gound with the longest wire coming to with in 4 to 5 feet of the ground which then is connected to a insulator and guyed down with nylon rope. Things seem to work fine and I'm able to make contact with almost anyone I hear. But like others I want to be able to do the best I can with what I have.
Does anyone have any suggestions on what I can do better, if indeed I need to.

Thanks and Best of 73's
Lonnie

According to the "Personal Radio Steering Group" (PRSG) which publishes a plain english instruction booklet on how to properly fill out a GRMS license form:

"The GMRS is available only for communications between MOBILE UNITS, or from one or more mobile units with a single land station. Land stations are PROHIBITED for communicating with each other."

The document can be downloaded from the PRSG bulletin board at (313) 995-2100.

I have been very pleased with my Radio Shack HTX 202.
It goes on sale for about $190 every month or so. It is a little
larger than the shirt pocket sized radios you can buy now, but
is an excellent radio. It has proven to have great range and I have
gotten many comments on it good quality "voice." A Radio Shack
is near just about everybody, so go take a look!

DTMF is a dual-tone scheme used to encode your keypad. Touchtone phones use
the same thing. You use it if, for example, you want to use a
repeater's autopatch feature and place a phone call ("patch") via
your HT. When you press a key, a two-tone AF signal is transmited and
must then be decoded at the receiver.

The CTCSS tone encoded squelch is used to control access to a repeater.
If a repeater is "toned," you must transmit a tone subcarrier along with
your normal FM signal in order to access the repeater. Most of the
time, this is used to reduce noise and interference going into the
repeater and causing it to retransmit the noise. Only toned signals
"get through." You can do the same thing on your HT -- only toned signals
that you receive will break your squelch. Seems like there are
30-50 different squelch tones that you can pick from when setting this
up. If a repeater is using a tone, you can find out what tone it is by looking
the repeater up in the repeater atlases that the ARRL and others sell.

Hope this helps. Congrats on getting your ticket! Start working toward Extra!

Gary:

You are correct that there is no net flow of current in AC waveform if you average over a full AC cycle. There is a net flow of current during the positive and negative parts of the cycle. This flow of current is what does the heating in the resistive components if any of the circuit attached to the source of current.

If I have a DC source that I connect with one polarity to a resistor for a while and then reconnect it with the other polarity fot the identical amount of time, I will have a net flow of current into the resistor of zero. I will have a net flow of current from the battery and this times the voltage of the battery is the power that is put in the resistor.

Jim

>ground.

You would only notice the problem if it was severe. With 100 watts, you likely won't get burns or RFI even with a little bit of RF floating around on the cabinets.

>Since my first post I have added a ground stake and ran a 12
>gauge wire from the ground post of the radio to the ground stake. It's
>30' long. Now everything I've read says you need to have a ground wire
>as short as possible in order for it to work. In my case 30' is as short
>as I can go.

That's not a ground at all on 40, 20, 15, and 10 meters, hi. But it is a ground that helps increase safety a little.

>This is why I was looking into the Artificial Gound. But it
>really didn't work as I expected it to.

All that does is tune out the reactance of the ground lead. It can not modify the resistance, or prevent radiation from the ground lead. At times it helps, at times it does nothing. In you case, I expect the latter to be true.

>My feed line to the antenna is
>also 30' long.

That's a good length for 40 and 15 (assuming surroundings aren't detuning it), and a bad length for 20 and ten. You could be more sure of the performance if you added a small choke balun of several turns of coax a few inches in diameter at the feedpoint. Wind the coax around a large diameter PVC pipe in a single layer.

That simple common mode choke coil helps keep the current in the antenna balanced and off the outside of the coax, and it is cheap.

I had a feedline connected to a 160 meter dipole at 300 feet on a tower. At low power, everything worked fine. When I ran a big amplifier the shield of the coax arced over to the tower about 100 feet down from the antenna. I fixed the problem by adding a choke balun, and by grounding the cable to the tower 1/4 wl below the feedpoint.

Source record: 202909

I am looking at buying a 2m mobile rig. UHF not necessary, neither a dedicated packet connector. Really just looking for a solid rig with good intermod filtering "out of the box". Prefer to buy new rather than used.

With this in mind, there is a Canadian dealer offering (for a limited time, limited quantity) a Kenwood TM-241A for $299Cdn. Is this a good buy?

I have seen a couple of different spec sheets on this model and there was a discrepency on the number of memory locations is it 20 or 40?

How does this rig compare to the Yeasu FT-2200M, the Icom IC-2000H, or the Alinco DR-130? Any comments on any of these rigs is appreciated.

Thanks,

Ron VE9ZX

>
> Rick KT2Q

I am completing a review of the 2 meter kit. The basic kit is $200 and an extra $50 I believe for the 35 watt amplifier module which fits on a large heat sink that attaches to the back of the rig.

The finished rig won't have all the bells and whistles of a mobile 2 meter rig.. no scanning, and right now no DTMF mike to go with it.. but it has internal provisions for tones and packet and they are looking to put a matching mike or mike kit out for it.

The rig does have 15 memories, is small and looks very professional (not like a kit) when completed.. does the offset and non-standard offset.

The rig is built in sections and you test each section and get it functional before proceeding.. I love this approach. The quality of all parts is excellent.. the manual is excellent. the original had a couple of minor errors, only one that would cause you desoldering problems.. but they have already done an addendum that caught all the problems I came across.. the Faxed it to me. The support is excellent.. if you run into a problem, you can talk to someone I believe who designed it.. but at least he knows about everything there is to know about the rig.

You only need a standard meter for most of the alignment. I found the alignment process for all sections extremely easy.

I loved building the kit.. it works great and the enjoyment I had building it justified its cost.

Sri for not responding sooner, I have noticed no delay at my 10wpm rate. Not
to say some speedy type 20+ may not notice it. OTOH, I'm not tech oriented
but my question is this:
Is the DSP (this or any model for that matter) active on transmit as well as
well as receive? I was under the impression it was for receive only.
Or I may be way off base on the impression I get from the above post. If I'm
off the mark, I apologize. But a very interesting question.

All answers/info appreciated.

I have no firsthand knowledge, but from what I've heard neither is a good rig. The RCIs apparently have problems with spurious emissions. I'm not sure what the problem is with the Emperor, but the advice I've consistently seen is that the Uniden HR-2510 is the best choice in this area.

> Also I need #s of some mail order places that sell 10m rigs and amps.

I'm a new ham, so I'm not sure if any of these guys sell 10m stuff, but here are some numbers:

Ham Radio Outlet - have several numbers for different areas of the country, but since you're in the West the number would be 1-800-854-6046

Amateur Electronic Supply - 1-800-558-0411

Amateur Radio Supply - 1-800-457-2277 (these guys are in Seattle, don't know how far that is from you)

Electronic Equipment Bank - 1-800-368-3270 - these guys sell lots of scanners/sw receivers as well as ham gear

And, if you're looking for 11m stuff (CB) as well, you might want to check out Copper Electronics, 1-800-626-6343

760. ? Best 2m/440 dual-bander?

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-13 00:00:00 UTC
From: shul9478@uidaho.edu
Message-ID: <shul9478-1304961427540001@xslip05.csrv.uidaho.edu>
Source record: 202713

I'm new to the hobby, and looking at getting (or having someone else get me, for lack of money) my first HT. I'd like a fairly nice unit, a dual-bander. I've been looking at the various manufacturer's offerings, and I think I've narrowed my choice down to the following:

Kenwood TH-79A(D)H
Yaesu FT-51RH
Alinco DJ-G5TH
Icom W31AH

I've been looking at the 'H' (5w, high power) versions, because I live out in Idaho, which has an awful lot of nowhere out in it. Is this a good/bad idea?

Also, I can't seem to find any information on Standard brand radios. Do they have any in this feature range that I should be considering?

I've heard that Kenwood radios are generally very durable, whereas Icoms are rather delicate. Is this true? Does it apply to the particular radios I'm looking at? How do the other brands/models stand?

Also, is there any particular brands/models I should avoid, because of problems with sensitivity/selectivity/intermod/overmod/anything else?

I've also heard of a problem with the TH-79A display. Has this been fixed on the (D) model?

While the others have a cross-band repeat, the Yaesu has a 1-way repeat as well. What is this? And I've heard of people killing their HTs using the repeat function. What is the typical maximum duty cycle for these type of radios?

Also, is the 'scope' feature that the Yaesu and Alinco have actually useful? How about backlit keys?

And lastly, how much use time I can expect from these radios on a charge?

Sorry for so many questions. I've tried to gather information from as many sources as I can, but I haven't been able to find much on the web, and none of the local libraries carry QST (to look up reviews). I plan to pick up some brochures with more details at the Lewiston (ID) Hamfest in two weeks, but until then I'd greatly appreciate any input anyone has (especially on the matters that aren't going to be mentioned in brochures, like durability and common failures).

Hi Gary,
Try answering questions I have, if you can. Otherwise, I'm outta here.
In article <1996Apr12.213306.20814@ke4zv.atl.ga.us>, gary@ke4zv.atl.ga.us
(Gary Coffman) writes:

>>No, the grounded end is NOT a high impedance point. The highest
impedance
>>point is the top.
>
>But wait, it's a halfwave, and you've been telling me that the impedance
>of a halfwave repeats at each end. So if you say it is high at the top,
>it has to be high at the bottom too. Can't have it both ways.

Sure it can. You created a mixture of two systems.

>Now lets take you at your word here and assume a halfwave grounded
>at the bottom does *not* then present a low impedance at the top.

You described the system Gary, but you fail to follow the criteria YOU
laid out. Since you want to talk about something other than shunt feed,
let me do that. My response was to the system you described. If you are no
longer talking about a shunt fed system, let me change the answer.

If fed at the top (ungrounded end) against a counterpoise of any sort, the
top of the vertical will be a low impedance. That low impedance will add
to the impedance of the counterpoise.

At the same time, since the base is grounded, it has to be a low
impedance. It has zero volts with respect to ground. When measured against
any counterpoise, it will add a very low impedance to the system.

>>>Childish comments deleted>>>>.

>Frankly, I believe that the bottom is also a high impedance from
>the only point of view that matters here, that of the currents on
>the conductor. Earth in and of itself has no particular impedance,
>high or low. It assumes whatever impedance is necessary to satisfy
>Z=E/I for the values of E and I measured across and along points
>in the mesh.

It has to be, by definition, a low impedance. At that point the antenna
and ground are in parallel. The antenna doesn't contribute anything at all
to the system. This is exactly why an UNGROUNDED half wave line feeding a
dipole divorces the common mode current from the feeder.

>The whole fallacy of your and Jack's argument has been this insistence
>on an absolute impedance for ground that is low. Impedances, like

voltages,
>are only relative to the two points across which they are measured. There
>aren't two points with Earth in between in this case, so we can say
nothing
>about the impedance of Earth from the POV of this circuit.

The earth (assuming we have made a good connection to it) is a low impedance. If you don't believe that, explain how we can feed a 1/4 wl vertical against earth. Explain why a 1/4 wl antenna fed against earth has HALF the impedance of a 1/4 wl antenna fed agaist a true image. Where is your "current mirror" in that example Gary?

764. Johnson LTR radios for sale/trade

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-13 00:00:00 UTC
From: ki5bd@aol.com
Message-ID: <4knnsu$8h2@newsbf02.news.aol.com>
Source record: 202765

I have the following radios for sale or trade. All operate on the Johnson Clearchannel LTR trunking system.

Uniden FPS 820 TS handheld (the big one) with DTMF and APX114 rapid charger.
$175

Uniden FTS 800 TS trunk mount mobile with DTMF mic.
$200

E.F.Johnson 8870 trunk mount duplex phone/radio with TD7 paging feature.
$200

E.F.Johnson 8870 with Telephone Interface Module (allows the use of any standard telephone equipment). Great for remote locations where there is no standard phone service. It works like a standard wall jack and allows the use of multiple phones, fax machines, modems, cordless phones or alarm equipment.
$400

All of these units would require programming by your local E.F.Johnson LTR provider.

Add $20 each for shipping.

Will trade for All Mode Dual band 2m/70cm ham rig.

Resond by Email to : KI5BD@aol.com

Gary Coffman (gary@ke4zv.atl.ga.us) wrote:

: We cannot directly measure a potential difference, we can only infer
: it indirectly by the charge displacements it causes.

Again agreeing with Gary on this, I'd repeat: you would have good company
if you believe that potential differences and the fields they imply
are simply mathematical models to explain the motion of charged particles
that we can actually observe. If you insist on thinking of a field or a
potential difference as "real," I have no trouble with that, but it
also doesn't bother me if you think of it only as a mathematical
abstraction that you use to explain the forces on the things (charged
particles) that we can see. But I do have a problem about "potentials
attracting" (or repelling) eachother. It's the charged particles
that interact with eachother through electrostatic and dynamic forces.

770. Yaesu FT-8500 noise?

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-13 00:00:00 UTC
From: jcupples@iphase.com
Message-ID: <jcupples-1304960838150001@va-dyn29.iphase.com>
Source record: 202771

Recently got a new FT-8500 dual band mobile rig.

I've noticed a low-level high frequency audio noise in the background, particularly irritating if using a headset, but audible even from the internal speaker. This noise is present whether or not the squelch is broken and is unaffected by changing the volume control setting.

If using only the speaker, this is not too irritating, as the sound is directional, and would not be obtrusive in a noisy mobile setting. I'd guess it to be 8 kHz or so, and pretty consistent in tone.

Has anyone else observed anything like this? My FT-51R HT is dead quiet when the squelch is unbroken, and I'm thinking of sending the FT-8500 back, but if it is something characteristic of this model I'd like to know...

Otherwise, the radio is OK, comments on my signal have been very good, and the rig is remarkably compact and solid mechanically. The MH-39 mike is nice enough, although this radio has practically no controls besides power and freq otherwise. It has a small and fairly quiet two-speed cooling fan in the rear heat sink, thermostatically controlled. Display looks/works good.

BTW, you do not get the remote faceplate kit except as an option.

cheers,

Jerry Cupples

Charlie made a good point.

A correctly placed "ground" could help prevent current from flowing down the line in the first place. It doesn't need to be a perfect ground, or even a real good one. It does need to be properly placed.

This is commonly done at microwave.

Why are you guys wasting time arguing terms when the problem is with someone's concept of RF circuit behavior? This seems like a Mexican Hat dance, or a Snake dance around the real issue. It even snakes all over the newsgroups in four or five places at once, like that is necessary!

>need to.

Sorry, Lonnie, we have drifted far afield from answering your question.
As you can see, it's not as simple as it looks. But lets cut to the
bottom line here. Things worked fine at your station without a "ground"
connection. Things still work fine at your station with a "ground"
connection. And tuning the "ground" lead with a artificial "ground"
tuner makes no difference. Seems like in practical terms you have
answered your own question. You don't need a "ground", nor do you need
to "tune" it.

As to the reasons *why* that's true, well just follow along with
the theory part of the thread and perhaps that will become apparent.
Or perhaps it won't, so let me say that with a balanced and reasonably
well matched horizontal antenna, ground doesn't play a significant part
in the antenna's operation except that out in the far field it gives
reflection "gain" that will affect the takeoff angle of the main lobe.

That's important for Dx. A lower takeoff angle allows longer skip,
and hence greater Dx potential on a single hop path. (On a multiple
hop path too, but that becomes complicated by the scatter at the
landing zones.) Anyway, the best thing you can do to get a lower
angle of radiation is to get the antenna *higher*, further from
ground, because that will lower the angle the most (up to a point

anyway, there is such a thing as an antenna that's *too* high, few of us will have the luxury of finding out about that first hand).

If you *do* start to suffer from hot shack problems, don't mess around with "grounds", cure the problem at the source by using a choke balun at the antenna feedpoint to suppress the currents attempting to flow on the outside of the shield. And make sure your antenna and feedline form a symmetric arrangement between themselves and ground (or any other conductor). This physical balance will give you electrical balance that will reduce or eliminate any currents that may be induced on the feedline.

There is one, and one only, reason why you want a good effective Earth connection at your station. That reason is electrical safety. Lightning is a discharge of the electrostatic potential developed between cloud and Earth. You want to give that discharge a good low impedance path to Earth that doesn't include such conductors as the innards of your equipment, or *your* innards. Use an entrance bulkhead as a ground window, suppress *all* cables entering or leaving your station to that bulkhead, and connect it via the lowest inductance conductor you can directly to Earth.

That's everything you need to know about grounding your station. Now if you choose to feed an unbalanced antenna, like a long wire, or choose to work a vertical against Earth, there are other things you need to know about grounds. But those grounds need to be at the *feedpoint* of those antennas, and not at the station. (In the case of the long wire, that *can* be one and the same, however. I don't recomend you try feeding a long wire from your elevated location. That *can* become tricky, and you might have to resort to that artificial ground tuner to make it work.)

Gary

Gary, you are begging the question a bit. I could also say that
you can only feel the depolarization of the neurons caused by potential
differences across them caused by the current. You can also measure
voltage by measuring the distortion of piezoelectric substances, which
does not involve a steady current (though it does involve a displacement
current). We can also measure voltage by measuring the force between
to objects at different potentials, which is somewhat similar, and does
not involve measurement current. In regard to the rock - we can put
it on a balance and measure the force, so we do not have to measure
its movement.

I would like to buy an Icom R-9000, in mint or better conditon (non-smoker). Please contact me by e-mail or at (815) 939-2006 or (815) 939-9723. Would "rjone1" please contact me. Thanks very much!

Jim N9CXU

782. Re:FS: lots of tubes

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-13 00:00:00 UTC
From: jim@rio.com
Message-ID: <4korn2$2er@wave.rio.com>
Source record: 202783

Thanks to the many who have responded to my ad. I think my mailbox has overflowed. I have never gotten
such a response to an ad placed on the net and I have been buying/selling pro audio gear and musical instruments
for about a year.

Anyway here's a list of the tubes. Compiled and entered into my computer using every spare moment for two
days. I think I have developed the very worthwhile abilitly to identify a 6AL5 from as much as ten feet away.
As many of you suggested, I have marked the tubes that were in matching boxes as NIB (new in box) all others
as used. One of the tube caddys is in excellent shape, it is labeled Pacemaker. the other one is water damaged
and virtually useless. I will try to send this list to individuals who responded.

If you want to buy the whole lot (not pieces) either e-mail me or call me at 541-687-8823.

I must say that I had no idea that the old tubes were worth much. I couldn't throw them out cause they
represented so much of my dad's history. I used to go up on the hill with him and adjust the antennas for the
cable feed when I was 6.

thanks for all your interest, Jim

```
5 Kikusui COS6100M 100 Mhz, 5-Channel Portable Oscilloscopes. Has up
to
12 traces. 5mv to 5V per division (1 mv with magnifier), 2% accuracy.
Extrememly light (only 21 pounds). Trigger lock allows for stable,
automatic triggering. Can display several lissajous patterns at once.
Meets military specifications. Great scopes, excellent condition.
$350.00 each. Please call Jon Friedman at (804) 340-7685 for more

I haven't experienced the noise you have mentioned, but I get audio feedback if I turn the UHF volume up past 3/4. It's a pain, but certainly acceptable.
If you don't like the mic, I suggest purchasing the FS-10 Smart Controller, jit looks weird, is a bit awkward to use at first, but easy to navigate the rigs features once you get used to it!

This may be some help

Gary

Most Common Failures and Cures for the Icom IC-751 & IC-751A

*Unless otherwise noted, the following failures and cures apply to both models.

Symptom: Distorted, or no RX/TX on one or more bands. Problem may be temperature related.
Probable Causes: 1) Bad trimmer capacitors on PLL unit. 2) Noisy variable resistor on PLL unit.
Cure: Replace plastic trimmer capacitors C78, C88, C97, and C107 with ceramic types. Remove excessive wax from around replacement trimmers to prevent wax contamination. We suggest using a 12pf trimmer for C97 instead of a 7pf as listed in the service manual. This will allow you to properly adjust the HPL lock voltage for that band.
Modification: If variable resistor R43 on the PLL unit is the 470 ohm type, replace it with a fixed-value 220 ohm version. If it's the 2.2k type, replace it with a fixed-value 1.2k resistor.
Remarks: While the PLL unit is lifted, we recommend soldering all joints in the regulator section as this area runs hot. Also, inspect electrolytic capacitors C128, C129, C132, and C137 in the regulator circuit for discoloration caused by overheating. Replace all overheated capacitors to prevent future failures.

Symptom: Erratic display i.e., frequency listed will be out of the normal operating range of the radio. Rotating the VFO knob may cause strange characters to appear in the display. Radio does not work properly. Cycling the power switch a few times may restore operation temporarily. Problem may be temperature related.
Probable Causes: 1) Cracked solder on RAM unit is causing logic errors. 2) Program in RAM unit is corrupted. 3) Burned/overheated R20 on logic unit is causing low voltage

in logic unit.
Cure: Check for burned R20 (10 ohm, 1/2 watt) on logic unit. If it looks OK, resolder cracked joints at J1 and J2 connectors on RAM unit, then reprogram. If this does not help, substitute RAM unit with a known good one. If the substitute RAM unit works properly, then the RAM unit must be replaced. If the substitute RAM unit does not cure the problem, there may be noise from the DC-DC converter causing the logic unit to glitch. Follow instructions for "No frequency display" problem.

Symptom: No RX audio in any mode except FM. No TX. Unit is not unlocked.
Probable Cause: PBT oscillator is not running.
Cure: Verify absence of 9.4665 signal at W86 on main unit in 751A, or W134 in the IC-751. Replace faulty X7 on main unit in IC-751A, or X5 in the IC-751.

Symptom: Frequency instability in USB mode.
Probable Cause: Bad trimmer capacitor in BFO section on main unit.
Cure: Replace plastic trimmer capacitor with a 30pf ceramic version and realign.

Symptom: Drastic change in audio frequency response between USB and LSB., i.e. USB audio has too much bass while LSB audio has too much treble. TX frequency response is also poor.
Probable Causes: Misadjustment of the BFO or PBT oscillator, or a faulty crystal filter FL-30 (or FL-80 in 751A) on the main unit.
Cure: Check adjustment of the BFO and PBT oscillator. If these are OK, then the problem is most likely in the filter.
Remarks: If the problem is intermittent, and the radio is an IC-751 (not "A" version), then the ground return path for the -5 supply between the display and main units may be poor. To cure this, connect a short wire jumper between the unused pin 2 at J2 on the display unit and chassis ground at the closest mounting screw of the main unit PCB. If no spare pin is handy for the connector at J2, the jumper may be soldered to the transformer shield of T1 instead.

Symptom: AC hum or buzz in transmit and receive audio when an internal power supply is installed.
Probable Cause: AC in being induced into the PLL from the AC wires and power supply case.
Cure: Twist the AC wires that run from the rear panel to the power switch and route them away from the PLL unit. Tape them up against the chassis if necessary.
Remarks: In some radios, especially older IC-751s, it is not possible to completely eliminate all AC hum when using

the internal power supply.

Symptom: No, or very low RX sensitivity.
Probable Cause: Bad components on RF unit, probable result of RF overload. To verify this, check DC voltages at D47 on RF unit. Correct voltages are: Cathode side- RX: 8.5, TX: 13.8. Anode side- RX: 9.0, TX: 9.5.
Cure: Replace all of these components on the RF unit: D42, D44, D45, D46, D47, Q15. Check C174 and C179 for leakiness. There may be other failures. Unit is not repaired until listed voltages at D47 are correct.

Symptom: Distorted RX on strong signals. BC band RX sensitivity may be low or marginal.
Probable Cause: Q15 on the RF unit has become leaky.
Cure: Check and replace Q15. If Q15 is leaky, there may be other problems on the RF unit. See cure for RX problem listed above.

Symptom: RX disappears when outer conductor of coax is connected to antenna jack. Inspection reveals 6 volts DC at the center conductor of the antenna jack.
Probable Cause: Shorted DC-blocking capacitor C40 on the ANT SW unit.
Cure: Replace the capacitor.
Remarks: There are probably other problems on the RF unit if this capacitor is bad. Check the voltages at D47 on the RF unit. Radio may have been struck by lightning or sustained a large RF overload through the antenna jack.

Symptom: RX cuts out randomly when turning VFO knob in IC-751A with UX-14 installed.
Probable Cause: Incompatibility between UX-14 and 751A is causing the PLL to unlock.
Cure: Turn off transceive mode on UX-14 (bank S1, switch #3 to OFF position)

Symptom: Hash noise in RX, birdies.
Probable Causes: 1) Voltage regulators on PLL unit are oscillating, producing noise on VCC line. 2) Overheated components and/or loose screws are causing the power supply to run noisy. 3) Noisy DC-DC converter on display unit.
Cure: Replace overheated C129, C129, C132 and C137 regulator filter capacitors on PLL unit. Inspect power supply for overheated components and replace them as needed. If the components look OK, tighten the screws that hold down the reg. unit. Don't forget to tighten the screw hidden beneath the wire bundle where the DC output lines leave the case. If none of these help, and radio is a IC-751 (not A version), then the display DC-DC converter may need modification. Contact Icom Technical support for update information.

Symptom: No receiver audio at all in IC-751A. Signals can be seen on S-meter.
Probable Cause: Cracked joint on main unit is causing no VCC the audio amp IC.
Cure: Resolder cracked joint at L46 on main unit. Repair damaged foil trace, if necessary. Re-route ferrite beads so they will not press down on L46 (or any other components) when the top cover is reinstalled.

Symptom: RX audio seems low in IC-751.
Probable Cause: Unit needs update to audio amp circuitry on main unit.
Cure: Contact Icom Technical Support for update bulletin.

Symptom: No TX output in all modes. Problem is traced to no output at J8 on the RF unit.
Probable Cause: Bad Q14 amplifier on RF unit.
Cure: Replace Q14. There may be other problems on the RF unit. Check the DC voltages at D47.

Symptom: Distorted/raspy-sounding SSB TX. Average talk power is low, even at higher mic gain levels. CW, RTTY and FM seem normal. RX in all modes is OK.
Probable Causes: 1) External Astron power supply needs additional RF decoupling. 2) No bias voltage to driver or PA transistors..
Cure: Install RF decoupling capacitors on Astron power supply (if used). If this does not help, measure voltage at bases of driver and PA transistors in TX SSB mode. Should be around .67 volts. O volts indicates trouble and probably a bad Q6. If problem is intermittent, check for bad solder at the legs of Q6, or D2.
Remarks: The driver and PA idle current was set too high at the factory in some IC-751s. (not A version). Align the idle current as per the service manual after repairs are made.

Symptom: When using an internal power supply, the power to the radio flutters on and off when the TX power output is increased toward maximum. Unit runs fine when the internal power supply is substituted with an external supply.
Probable Cause: Cracked solder in the current-sensing circuit of the power supply is shutting it down prematurely.
Cure: Resolder joints at the .0012 ohm resistor, R26 inside the power supply.
Remarks: This resistor appears as a metal bar soldered to the bottom PC board. Solder the edges of the bar BEFORE the holes at either end.

Symptom: TX oscillations/spurious output.
Probable Causes: 1) Open resistor or faulty electrolytic capacitors on PA unit. 2) PA unit needs modification. 3) Bad drivers or PA transistors. 4) Burned components on the

ANT SW unit.
Cure: Check the value of R22 (4.7 ohms) on PA unit. (This resistor may look OK but still be open.) Replace C18 and C25 on the PA unit if they appear swollen or overheated. Modification for old IC-751: Install a metal film, 220-ohm 1/2 watt resistor parallel to C6 on PA unit if there isn't one installed already. Inspect the D4 area of the ANT SW unit and replace any burned components. If none of these solutions solve the problem, disconnect the J10 on the RF unit and see if the problem goes away. If it does, then there is a problem with the TX/RX switching on the RF unit. If disconnecting J10 doesn't help, then most likely either the drivers or PA transistors are bad, especially if the ALC meter deflection is low.
Remarks: The spurious output may also be caused by incorrect band switch voltage to the low-pass filter unit, or even faulty/burned components on the filter unit itself. The above causes should be ruled out first since low-pass filter failures are uncommon in the IC-751(A).

Symptom: Intermittent low FM TX output power in IC-751.
Probable Cause: Bad relay RL1 on FM unit.
Cure: Replace bad RL1 (221B-D009-M)

Symptom: No TX output at all in RTTY or CW modes. SSB and AM are OK.
Probable Cause: Bad carrier generator crystal on main unit.
Cure: Replace bad X1 on main unit.

Symptom: No frequency display, only decimal points. Problem may be intermittent or temperature related.
Probable Cause: Display DC-DC converter has noisy output.
Cure: Replace all of the following dried-out electrolytic capacitors on the display unit: C17, C18, C20, C21, C22, C23, C24, and C25. (These capacitors are light yellow when they are new. Capacitors that have turned brown are old and dried-out.)
Remarks: While servicing the DC-DC converter section, be on the look out for cracked solder joints, as this section of the radio tends to run hot. Also, it would be a good idea to reprogram the RAM card after servicing the DC-DC section.

Symptom: Poor carrier suppression in SSB mode in IC-751. Will not adjust properly.
Probable Cause: Main unit needs factory update.
Cure: Contact Icom Technical Support for update bulletin.

Symptom: Low garbled audio sound in speaker/headphones in SSB TX, even with monitor turned off.
Probable Causes: RF feedback. 1) Inadequate station ground. 2) External Astron supply needs RF decoupling. 3) Main unit needs factory update (IC-751 only).

Cure: Check station ground. If an Astron power supply is being used, add RF decoupling capacitors to output terminals to prevent regulation problems. If the problem occurs in an IC-751, a factory update may need to be installed to the main unit. Contact Icom Technical Support for this information.

Symptom: Radio seems to be stuck in "scan" mode.
Probable Cause: Bad IC2 on the logic unit.
Cure: Replace IC2 (RP5G01-007).

Symptom: Loud, high pitched squeal emanates from inside radio.
Probable Cause: DC-DC converter transformer has a loose core.
Cure: Replace T1 (TO-9) on the display unit.

Symptom: VFO tuning is erratic, sometimes skips when changing frequencies or bands. Display does not increment smoothly when VFO knob is turned slowly.
Probable Cause: Dirty rotary encoder.
Cure: Remove white plastic cover from back of rotary encoder and spray clean the carbon track with Blue Showers solvent. Spin VFO knob vigorously while spraying.
Remarks: Do not let solvent saturate the display unit or allow it to come into contact with the plastic display lens. Stuff a paper towel between the rotary encoder and display unit to catch spray run-off.

Symptom: Missing segments or mode indicators on display. Problem may be intermittent.
Probable Cause: Bad connection between logic and display units.
Cure: Check the connectors J5 and J13 on the logic unit where the flex cables to the display unit are attached. If they look OK, and none of their connector spring contacts flattened, replace the flex cables.

Symptom: Low mic gain when using Heil mic element.
Cure: Install modification: In 751, change value of R264 on main unit to 200k. In 751A, change value of R21 on AF-VR unit to 47k.

793. Re: cellular phones

I think a FAQ would be a good idea and I think it would be neither short nor
comical.

>Anyway, I can alsmost gaurantee there are no keyboard mods to do anything
>with a cell phone besides make cell phone calls. The company that wrote
>the code in the phone probably wouldn't want to spend hundreds of extra
>man hours on a 'hidden' feature' that has no additional benefit to their
>end users.

There are test modes that are useful. For example, to load non-standard values
to the PLL's and to force transmit. You could change a ref xtal and force xmit
to see what you have accomplished (xmit pwr, freq).

Remember, the duplexer will probably have to be removed and a T/R relay
or PIN diode switch installed.

>As far as your other mods, the chances of modifying the phone to work
>900Mhz are pretty slim as well.
>
>Big problem #1: The phone's RF section will be optimized to transmit on
>824 - 849 MHz. If it could be re-tuned to a higher frequency, it would be
>a very poor performer in the 900 MHz amateur band. You would be better off

Do you know this for a fact or are you simply guessing? Are you giving up
before you start???

>Big problem #2: There is probably a PLL controlled by a microprocessor
>that you will have to reprogram. That is assuming it runs code from an
>PROM that you can remove and reprogram. It may have One Time Programmable
>(OTP) memory built in the processor, so you can pretty much toss that CPU
>in the trash, and redesign the entire digital section around another CPU
>that you can program yourself (not an easy task -don't forget about the SW
>engineer that would need a couple of hundred hours just to add your
>scanner function)

Of course there is a PLL controlled by a micro. Any yes, you will have to
completely toss the code and do a complete rewrite. But you can salvage
many subroutines from the old eprom!

Step 1

Identify the controlling micro and get it's data book which has the instruction set.

Step 2

Get a disassembler for that micro (available from many mfgr's BBS systems and also as frreeware). Disassemble the eprom.

Step 3

Identify as many similarities in subroutines as you can. Get the book "Mobile Cellular Telecommunications Systems" by William C.Y. Lee, ISBN 0-07-037030-3, McGraw-Hill. Identify which subrs are for writing to the display, which are for eeprom, and which are for keypad data scanning and handling.

Step 4

Make a new eprom with very basic functioning - I suggest trying to get the keypad to write to the display - to test how far you have understood things. Remember to disable all the checksum and radio health lockouts.

Step 5

Play until it does what you want. Remember most of the code is for handling the cellular AMPS protocols and is not necessary for ham radio usage.

>
>Big problem #3: The display -Assuming you want some useful information on
>the display like what frequency you're listening to, you'll have to

>on getting photo's f alien from the white house then info on a propietary
>LCD!)

My experience says otherwise. Most of the controllers I have seen are very similar to the Hitachi one. And all have available data sheets describing in excruciating detail how to use them.

>I could keep going with more gory details, but I think you get the point.

I don't get the point. To modify a cell phone to do ANYTHING different is an unbelievable learning experience in microcontrollers and equipment design. The time you spend may be better spent if all you want is a quick radio, but cannot be beat for pure satisfaction and learning.

..Peter

PS, yes, I have done this.

>>balanced at both poles. Nothing is attempting to draw more current
>>from one pole than the other, therefore there is no need for any
>>"return" current in order to balance the transmitter. **This
>>condition is satisfied whenever coax is attached to the
>>transmitter.**

>Ok, so if we believe this,

Gary, if you don't believe that the currents on the inside of the coax
are forced to be equal and opposite by the internal fields, we can
stop here. This is one of the basic attributes of coax and you should
address this issue for yourself post haste.

>there can be no current flowing down the outside of the coax because
>all the current that came up to the load on the inner had to go back
>down on the inside of the outer, and vice versa on the other
>alternation, because you say coax *forces* this condition.

You've reached another incorrect conclusion through the use of
ambiguous rhetoric. Your phrase "all the current" implies that the
current has an identity, that current "Jones" is flowing out of the
transmitter on one pole, therefore all of current "Jones" must return
to the transmitter on the other pole.

In fact, there is no identity, the two currents only need to be equal
and opposite. This means that the return current that flows back down
the inside of the shield can be drawn from any source whether it's the
leg of the dipole, the outer shield, or whatever. Regardless of the
number of sources, the total current reentering the inner shield of
the coax will always equal the current on the center conductor.

Incidentally, I will appreciate it if you don't nitpick the preceding
paragraphs from the standpoint of definitions or atomic theory. If
you disagree with what I've said, YOU must explain how shield current
can flow in the presence of a coaxial line that forces equal and
opposite current at each pole of the transmitter. Further, you must
explain why a transmitter that *always* sees a balanced load at the
input to the coax would require additional return current from the

end of the cable attached to the antenna.

>>Please stop this nonsense about some sort of external loop that
>>must be completed. It is an instinctual concept that does not exist
>>in a coaxially-fed system.

>Your paragraph 2 then states that coax *forces* the
>currents on the inner and the inside of the outer to be in balance,
>but that leaves I + (-I) = 0 current remaining to flow down the
>outside of the coax outer.

The fact that the current in the coax can be represented as 1+(-1)=0
has absolutely nothing to do with the dispersion of the current in the
load(s) outside the coax.

<rest based on incorrect conclusions that I have explained above>

>As a hint for those playing at home, an understanding of what we
>really mean by AC "current flow" is a key to understanding what's
>really going on.

There's no small irony in that statement, Gary. Unless you abandon
this discussion prematurely, I think you'll eventually regret it.

73,
Jack WB3U

795. AEA DSP-2232... New S/W out there???

>flow of current into the resistor of zero. I will have a net
>flow of current from the battery and this times the voltage of
>the battery is the power that is put in the resistor.

Yes, Jim, that's a good model. Now lets say you don't leave
one polarity of the battery connected to the resistor long
enough for the current to reach the other end of the resistor
and return to the battery before swapping terminals. Now what
happens?

That's the situation we run into at RF where the cycles are
rapid and the "resistor" and its leads are long. Now there
is no net charge flow through the external circuit even for
partial cycles.

There *is*, however, still a net charge flow in the battery.
That flow is the result of temporary charge *storage* in the
inductance and capacitance of the external circuit, which we
term reactive or "wattless" power, and the heat loss through
part of the resistor from which the charge enters and then
reverses and exits back to the opposite polarity of the battery
(which is now, of course, on the same terminal from which the
charge entered the external circuit). The latter represents real
watts lost to the external circuit while the former represents
an internal loss required to overcome the VARs in the external
circuit.

So we can still transfer real power from the source to the
external load without a net charge flow in the external circuit.
And if we replace the battery with an alternator, there will
be no net charge flow in it either, but we will still transfer
real power from it to the external load.

Now since by definition P=IE, and P is non-zero, then I must
be non-zero too. So I doesn't necessarily mean a net charge
flow in AC circuits, IE AC *current* is not a net charge flow
as it is in DC circuits. But I is *defined* as coulombs/sec
(amperes) past a point, so it would seem we have a contradiction.

I'm tempted to let the way out of this dilemma rest as an exercise
to the reader. I will give a hint, however, and add that it is all
a sign of the times (or is it the time of the signs?). :-)

Gary

It certainly can be done, just remove diode D59 and reset the microprocessor.
Whether it can *legally* be done will depend on what the rules are in the
nation where your craft is flagged, IE does the nation have a Type Acceptance
requirement for marine radios like the US does? If so, you're out of luck,
if not, then no problem.

Gary

Sb: FT890 MODS

YAESU FT890/AT mod. TX 1,5 to 30 MHZ.
==========

- Disconnect FT890 from all connections.

- Open tranceiver like explained in your "OPERATING MANUAL".

- Locate on the "CONTROL UNIT" jumper point JW 3001 and close it with solder.

- Close tranceiver back and reconnect power.

- Push PROC, AGC-F, IPO, ATT while power ON.

- Now the display shows two digits of numbers and tree of letters (i.e 13 OFF)
Rotate main knob and set the display to "02 ON". Now press the PROC button.

- Power OFF and then back ON. It's all!

- Now every time you want, you can change the programation, but you will
allways lose the memories.

- Other settings than "02 ON" are of no interest. This one give you 100 w
and automatic antenna tuning between 1,5 and 30 mhz.

73's de Phil, F1LOU @ ON7RC.BT.BEL.EU
==========
Note: I haven't tried or verified this, proceed at your own risk, and

do not transmit outside of legal bands! WA2ISE

>>>impedance point is the top.
>
>Tom, you've made an error in this statement. Both the top and bottom
>are low impedance points. The bottom is low impedance because it's
>grounded, and the top repeats it.

Ohh, I hate to defend Tom, but here goes. Jack, what is the magnitude
of current flow at the point of an open circuit? (Zero, or close to
it considering corona effects) What is the magnitude of voltage at
an open circuit point? (Maximum) Now what is the impedance if Z=E/I?
(Very high.)

There's no way you can get around the fact that current goes to zero
at the open end of an antenna, Jack. There's no place further for it
to go, it has to stop there and be reflected (unless it arcs into the
air by corona discharge, and to do that the antenna end point voltage
has to be *very* high). So we can only conclude that the open end
point of the antenna *must* be a high impedance. There's no other
choice.

>>But wait, it's a halfwave, and you've been telling me that the
>>impedance of a halfwave repeats at each end. So if you say it is high
>>at the top, it has to be high at the bottom too. Can't have it both
>>ways.
>
>He made a mistake in this post, Gary. The true operation of the tower
>agrees with his previous descriptions of a halfwave conductor. The
>error should be obvious by virtue of the fact that a 1/4 wave vertical
>exhibits a high impedance at the top.

Of course it does, it's an open circuit there. It has no choice. And
neither does the halfwave. It's an open circuit at the top, so that
has to be a high impedance point for it too. It can't be anything else.
Current can't flow any further.

So, both antennas have a fixed high impedance at the top that cannot be changed. Now applying wave reflection theory, that means that 90 degrees down from the top will be a current maximum/voltage minimum, and hence a low impedance point. Has to be, it's the law. Now 180 degrees down from the top, wave reflection theory tells us we must have another current minimum and voltage maximum, a high impedance, have to, there's no choice, it's the law. So the bottom of a halfwave vertical is a high impedance. No matter what it is connected to at the bottom, it can't supply current to it because it is at a current minimum, is a high impedance source, and practically nil current can flow. Has to, it has no choice, it's the law. The open circuit at the top *forces* the current into this distribution. There's nothing you can do at the bottom to change it.

> <self-congratulations deleted> <g>
>
>>Frankly, I believe that the bottom is also a high impedance
>
>This is ridiculous. The bottom is ground. <sigh>

So what? There's nothing, repeat nothing, magic about ground (dirt). It's just a poor conductor that happens to be large.

>>from the only point of view that matters here, that of the currents
>>on the conductor.
>
>Point of view doesn't matter. Current will be maximum at the bottom.

Not just wrong, but dead wrong. Current will be maximum halfway down the 1/2-wave antenna, just as the little diagrams in the antenna books show it to be, just like they show current to be minimum at top and bottom. Has to, can't do anything else, it's the law.

>>Earth in and of itself has no particular impedance, high or low. It
>>assumes whatever impedance is necessary to satisfy Z=E/I for the
>>values of E and I measured across and along points in the mesh.
>
>We're talking about earth ground, not the resistance of a handful of
>dirt. RF current on a single conductor will readily flow into earth,
>never to return.

If you say so, Jack, but darn little of it from a high impedance source. And it somehow has to pass through that "dirt" to get to your mystical "earth ground", and that dirt is a darn poor conductor, with a conductivity of about 0.001 S/m. If you oppose a big enough "plate" to it, though, it's a fair to middling capacitor, which is why buried radials work.

>>The whole fallacy of your and Jack's argument has been this
>>insistence on an absolute impedance for ground that is low.
>
>When's the last time you received an RF burn from earth ground?

About the same time I got a RF burn from a window pane. Neither conduct worth a darn, so why should I expect to get an RF burn from them?

>Gary, you have just made me very glad to be on this side of the
>argument. ;)

And you have made me very happy I'm on this side (impedance at the open end of a resonant halfwave antenna low indeed! chortle, snort) I'd like to see Tom's face when he reads all this. :-)

Gary

It appears that way only if you sum the currents after assigning "-"
and "+" designations. That's not correct, because this particular
concept of labeling is only appropriate when two phenomena occur
simultaneously. When that's not the case, only absolute values can be
applied.

>
>Voltage is not a substance. It is a name for the UNIT OF MEASURE (like
>"inch") for the ElectroMotive Force (EMF).

Yeah, sort of, but that's not telling the essence. It certainly gives the wrong impression. The volt isn't a unit of force, it is a *work* function that measures how much work it takes to move one coulomb of charge a specific distance against a specified field gradient. It has units of J/C (joules per coulomb). Work is, of course, force*distance, so force is certainly part of what constitutes the volt, but so is distance, the two end points locating Vab or the *potential difference* of the field gradient across which you are measuring. Thus the volt has no meaning unless it is measured between *two* points. There can be no naked potential.

You always have to ask, "relative to what?" when talking about the voltage at a certain point. And you are perfectly free to choose that "what" to be any point you like, and you'll get a different voltage for every different "what" you choose (assuming the points chosen don't form an equipotential surface around the other point). However, if you don't choose the "what" carefully, the voltage you read may be meaningless to the circuit in question. That "what" has to be another point through which the charge represented by the coulomb part of the volt can move, IE the point must be inside the topology of the circuit where Kirchhoff's laws hold, if it is to have any meaning to the circuit. In such a circuit, charge must be conserved.

OK, now that the FT-50R is out, we need to move on to something else.

How about this: The FT-3000M is really cool, and it is a 2-meter transceiver that followed the FT-2500. So, maybe there will be an FT-9000M, to follow the current FT-8500 model! Of course, the 9000 will have new features like a 70 watt output power setting! There we go.

810. FS: Large MILITARY COMM SHELTER

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-13 00:00:00 UTC
From: louis@postoffice.ptd.net
Message-ID: <4kpb4j$fog@ns2.ptd.net>
Source record: 202811

I acquired some military shelters that I had planed a use for, but I did not ever see the project through. I
am selling these shelters and thought you might like to check out a few photos of them. If you click on the thumb
nail you can see the larger picture in 800 x 600 resolution. The shelters are rated to block Rf frequencies
up to, I believe, 1.3GHz and at 120db of attenuation. These would make Ideal radio repair rooms. The construction of
the units are double aluminum clad over a foam core with an outer kevlar skin (Bullet resistant!). In pictures 8 and 9 you
will notice that the shelter can be used with a 40 foot Wil-Burt pneumatic 9 section mast. I am selling these masts separately
if desired. If you would like the shelter with out the mast I can reduce the price some what. These masts are like the
ones on the news vans, except that these are built to Mil Spec and the original cost to the defense contractor was $20,000 each.
Don't worry that is not my asking price.

I will sell you the mast separately for $2,500
I am asking $5,000 for a shelter with a mast, and I am asking $3,500 for a Shelter with out the mast.
If anyone would like more details, I can be reached at (717) 629-7212 ask for Louis or E-mail louis@postoffice.ptd.net

To see photos of these shelters use your web brouser and go to this URL

http://home.ptd.net/~louis/forsale/forsale.html

> that will nable me to use the phone as a scanner? Failing that, what mods
> would be necessary to change its operating frequency to the 900 meg ham band?

Somebody should write an FAQ on what you could do with an old cell phone.
It would be really short or really comical.

Anyway, I can alsmost gaurantee there are no keyboard mods to do anything
with a cell phone besides make cell phone calls. The company that wrote
the code in the phone probably wouldn't want to spend hundreds of extra
man hours on a 'hidden' feature' that has no additional benefit to their
end users.

As far as your other mods, the chances of modifying the phone to work
900Mhz are pretty slim as well.

Big problem #1: The phone's RF section will be optimized to transmit on
824 - 849 MHz. If it could be re-tuned to a higher frequency, it would be
a very poor performer in the 900 MHz amateur band. You would be better off
building your own RF section.

Big problem #2: There is probably a PLL controlled by a microprocessor
that you will have to reprogram. That is assuming it runs code from an
PROM that you can remove and reprogram. It may have One Time Programmable
(OTP) memory built in the processor, so you can pretty much toss that CPU
in the trash, and redesign the entire digital section around another CPU
that you can program yourself (not an easy task -don't forget about the SW
engineer that would need a couple of hundred hours just to add your
scanner function)

Big problem #3: The display -Assuming you want some useful information on
the display like what frequency you're listening to, you'll have to
understand how to program or control the display. LCDs typically have
there own little controller with it's own command language. You'll need
information on that)not easy either -you probably stand a better chance
on getting photo's f alien from the white house then info on a propietary
LCD!)

I could keep going with more gory details, but I think you get the point.

So what are you left with?, A keypad, a microphone, a speaker, a battery,
a handy little case, and an antenna; not much.

-BP

Gee....what memories....

I haven't been licensed really that long. Got my Novice ticket in December of '81...uh...after passing the exam in August (another story) but the day I received my ticket I made the comment to one of the local hams in my area that "all I needed now is a transmitter."

Lo and behold....within hours there was a knock at my front door. When I opened the door there was no one there. There was, however, this GIANT monster sitting on the step....I guess it must have weighed about 75 pounds or so. A Johnson Viking II.

Good thing there was a ham, WB8FBN (Fly By Night) who lived across the street from me. I called C.Q. (Chris Quintin--Smith) on the landline and told him that I had a transmitter anonymously delivered to my doorstep and no idea how to use it. Wasn't long that I was searching through my collection of crystals looking for one that would put me on a frequency I was authorized to use. Closest I could find was 6906.667 KC. It was then that I learned about using Comet and the glass top on my desk to grind the crystal so that it would work within the 40 meter Novice band. I frosted the heck out of the lower corner of the glass top...hi hi...but it was worth it.

With Chris' help, I ground it so that it worked on 7.155 MHz....woops...too high. A little pencil lead on the quartz wafer and

we got it down to 7.129 MHz. The crystal is sitting in front of me right now as I am typing this.

I had a Realistic DX-300 receiver that had a fairly decent readout. Chris went back home and I called him on the landline to let him know when I was ready to make my first contact as a ham. On December 14, 1981 with Chris instructing me I called CQ CQ CQ DE KA5MWD KA5MWD K and waited.

Hands shaking, forehead sweating, at 0100z I heard KA5MWD DE KA7FXV KA7FXV KN Not sure of what to do next I asked Chris for help. I still needed a little coaching from him on my second QSO which was eight and a half hours later but after that I was ready to solo...and I did.

Wouldn't mind having a Viking II again. I still have the crystal. As a matter of fact I have many crystals that would work. Thanks for letting me remember my beginning in ham radio with this "boat anchor."

Guess I'll just have to be contented with my Drake TR-7 and with bringing the FT-1000MP and other radios home from work on the weekends. :)

Huh? You seem to think that wires are like water hoses with electrons
squirting out of the end. The electrons go -nowhere-. They don't move.
They vibrate about equilibrium positions. It's the electromagnetic
-wave- which moves. Like waves on water. The water doesn't go anywhere.
Only the waves move.

Mike

This has nothing to do with electricity. NOTHING can be detected by any
means other than by its effects.

)This does not mean that voltage is not a substance, however. I used
)the phrase "essential essence" intentionally, as this is the very
)first definition of "substance" according to my copy of Webster's.

Voltage is not a substance. It is a name for the UNIT OF MEASURE (like
"inch") for the ElectroMotive Force (EMF).

)Also, your reply doesn't respond to my statement that voltage is
)attracted to all unlike voltages. Are you disputing this or is it
)actually a similar disagreement regarding definitions? I reread your
)previous post, but I'm still not sure.

Voltage is not attracted to anything.

)Incidentally, unless I'm missing some of your articles, I haven't seen
)a reply to either of my posts discussing the impedance of the
)transmitter chassis (one was the article quoting the Antenna
)Handbook). The common mode impedance of the chassis is one of the
)basic issues behind our disagreement regarding the correct shield
)length. Have you changed your position on this?
)
)73,
)Jack WB3U

I have never seen the phrase "common mode" used in this sense before.

Mike

)The discussion regarding artificial grounds and coax shield currents
)has raised a related issue that I think is widely misunderstood.
)
)First, it was stated in the other discussion that feedline currents
)radiate because they are unable to enter the transmitter and return to
)their source. I have disputed this because there are many openings
)and pathways into the typical transmitter for current flowing on the
)outer chassis. If the current is attracted to the inner chassis, and
)it appears that it is, it can find a way in. The evidence of this is
)that RF in the shack often causes the internal workings of the
)transmitter to malfunction. In addition, removing the cabinet of the
)transmitter will typically have little or no effect, good or bad, on
)the RF in the shack.

ALL alternating current radiates. With coax, you have (nearly) equal
currents flowing in opposite directions, with one enclosed in the other.
Each of the currents then radiates an electromagnetic wave of (nearly)
equal amplitude but (nearly) opposite phase. These interfere
destructively, resulting in (nearly) zero radiation from the feedline.

DRAKE R8A Shortwave Communications Receiver (Latest Model!)
100-30,000 KHz, AM/FM/LSB/USB/CW/RTTY Modes!
Includes Drake's optional internal VHF module, adding
coverage: 35-55 MHz, and 108-174 MHz, including Aircraft!

I purchased this brand new just last month (Mar 96). I'm
forced to sell it due to loss of employment.

Including tax, I have $1,351.50 invested!
I am willing to sell it for only: $950.00 [firm]
I will also pay standard UPS, insured shipping, anywhere
in the U.S.

Bill Crocker

No, the Volt is the unit of measure. Voltage is a synonym for EMF.

Also, I'm not the person who brought the term "substance" into this discussion and I agree that it sounds odd when it's applied to voltage. Nevertheless, voltage qualifies because it is the "essential nature" of the conductors under discussion. If you disagree with this, Webster's the guy you want to talk to.

>Voltage is not attracted to anything.

My statement was intended to convey the idea in layman's terms. From that perspective, it is not inaccurate and I will continue to use it when appropriate. I apologize if you find the wording annoying, but the statement is useful in describing the cause and effect simply and in a way that no reader will misunderstand.

>I have never seen the phrase "common mode" used in this sense before.

The current (and thus voltage and impedance) that we were discussing is antenna current.

73,
Jack WB3U

>Gary

They certainly do matter Gary. An RF signal can not be treated like a dc or low frequency ac signal. We can't "ignore" the impedance of other objects just because they aren't connected by a return wire to the source.

The whole problem is the connection between the antenna and any other conductive object with a relatively low impedance.

If what ***you*** say is true:

>and the electric field gradient, if any,
>it may offer has no direct relationship to the charge, and hence current,

>in the circuit.

1.) Some antennas would simply quit working (some have no return path).

2.) We couldn't draw an arc to an insulated screwdriver from an antenna (it has no return path).

3.) If we hung a open ended wire from one terminal of a dipole at the center insulator, no current would flow in that wire.

4.) If a grounded wire was hung from terminal of a dipole at the center insulator, no current would flow in that wire if the transmitter was isolated from that wire.

How do you explain effects like these, that we all know exist, if your last paragraph is correct?

If you last paragraph is correct, explain how a "floating" tie wire on an electrical line can actually arc to the wire it's wrapped around! Where is the return path Gary?

jackl@pinetree.microserve.com (WB3U) writes:
>
>Tom, you've made an error in this statement. Both the top and bottom
>are low impedance points. The bottom is low impedance because it's
>grounded, and the top repeats it.

If fed at the top (ungrounded end) agaist a counterpoise of some sort, that is correct Jack. But remember I was replying to Gary's example of a shunt-fed tower. Not a top feed arrangement. Because of that, there has to be zero common mode current at the top.

At the same time, since the base is grounded, it has to be a low impedance. It has zero volts with respect to ground, it is grounded. What it behaves like Jack, depends precisely on how and where it is "fed". Remember Gary declared the feed arrangement to be a "shunt fed" system.

There are only two rules we can declare from such a **nebulous** antenna description:

1.) The very top (open end) of the antenna must have zero current. This is because there is NOTHING beyond the end.

2.) The bottom of the antenna is a low impedance. This is because there is a direct connection to a low impedance.

It's silly to get sidetracked with an antenna that is full of the principles causing confusion in the first place. The problem is more basic than something as complicated as a shunt fed vertical. Especially troublesome is the fact Gary created an example that can only be analyzed with common mode and differential mode currents!

Let me explain how such an antenna would work Jack.

Imagine a shunt wire connected to the middle of the tower. At the point of connection, the BOTTOM 1/4 section of the antenna presents a high impedance, since it is a 1/4 wl section with the bottom connected to a low impedance. The TOP half of the antenna presents a low impedance, since it is an open ended 1/4 wl. Most of the current from the shunt feed wire will flow into the top half of the antenna. The common mode current distribution of the entire structure will appear almost like a 1/2 wl vertical.

Connect the shunt wire to the very top, and you have a shorted transmission line. The only radiation will be from imperfections in the system. The differental mode currents will be maximum at the top and

bottom, the very small common mode currents will be minimum at the top.

Connect the shunt feed wire at the bottom and we have a short. Nothing will radiate or be excited. Feed it anywhere in between, and we have mixtures of the three different systems.

Please read what Mike wrote. That's exactly how ANY shield works.

Even the cabinet of the rig works that way. Without equal and opposite
fields, a shield will not work.

That is the reason current stays on the inside of a coaxial line, the
reason a transmission line does not readily radiate, and the reason
shields work.

Hi Bill;

I know I am late on this thread but I must put in my "two cents".

I have had my Omni VI since they first shipped in the summer of 1992), (yep I am one of the first) and I can whole heartedly say that I LOVE EVERY CUBIC CENIMETER OF IT.

I have been hamming since 1961 and have had a variety of rigs over the years. In the early seventies I went "the way of the Jap rigs" and I can tell you that the fun I had previously enjoyed in Ham Radio declined went away.

The Jap rigs did (and still do) lack engineering quality and true inovation -- i.e. if they can't copy it from us you won't see it in their products.

When I went looking for a new rig in early 1992 Ten Tec had just announced the Omni VI. I decided on the spot that I had to have one. It was the perfect rig -- well thought out (hear me Japs) and not a too many bells and whistles most of which you will never use.

Well when I finally received my Omni VI(there was a waiting period then since demand was so high) I decided that all my Jap stuff had to go "yesterday if not sooner!"

I sold some, gave some away, and since there is not a big market for most Jap stuff, I wound up throwing a lot of it into the trash can!!!

Since I got my Ten Tec Omni VI Ham radio has become FUN again!!!! I have since bought their six meter transverter kit which is also great (better than the kits from Heath) and I can't wait for Ten Tec's next HF offering.

This was my two cents... or was it three!!

I have a BTI (Brad Thompson Industries) LK2000 2KW linear for sale. For those of you that may not be familiar with BTI - this amp looks a lot like a Henry 2K. It is meant to sit on the floor and is on casters. This amp is of late 1960's vintage. It uses one 3-1000Z as the final output tube but it can also use a 4-1000Z. This unit covers 10-80 meters and will run 2KW all day long. It can be configured to run 120 or 240 volts and has a built in thermostatically controlled cooling blower. The only problem with the unit is that the transformer has a short from the secondary to core so the core is at about a 600 volt potential. The transformer has been isolated on nylon standoffs so that a new transformer or rewinding could be avoided. The transformer is enclosed. Make an offer.

835. Kenwood TS690 - s meter adjust??

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-14 00:00:00 UTC
From: FCFB17A@prodigy.com
Message-ID: <4kpi21$1e88@usenetp1.news.prodigy.com>
Source record: 202715

I have a Kenwood TS690 that has a very stingy s meter. I bought it
new and have had it a couple of years. The receive seems fine though,
just low s meter reading. It does'nt bother me enough to send ot back to
Kenwood though. Does anyone know if it is possible to adjust this myself
by perhaps adjusting one pot without affecting anything else? If so I
would like to know which pot to adjust. I have manual and schematic but
don't know enough to find it without some help. Maybe someone has a
service manual with the info I need. I would appreciate any help. Thanks!

> -- Mike Fallavollita
> mikef@microtech.com
i too, have a '59. as the other reply mentioned, what i have is a
connector with 2 turns of 18 awg wire just larger than the coils on
the '59. connect this connector to the antenna coax and bring the
'59's coil to about 1", as you sweep thru the frequency dial, there
will be a pont where the meter will "dip", this is where the antenna
is hogging power from the meter. you'll need to set the "sensitivity"
knob to get the meter about 1/2 way up before you couple to an
antenna. another neat thing to do is to make an l/c circuit (obviously
do the math to see where it should resonate) and see how resonance
works. a valuable tool have a "standard" capacitor, like a 100pf
silver mica, and you can find unknown inductor values by looking for
resonance. the same goes the other way too, standard coil value,
unknown cap value.

RCA WT-100A and/or Hickok 700 tube tester wanted. Seeking unit in good running condition, needing some repairs or for parts (if I later come across a working unit). Willing to swap for something or please state a fair price for the respective unit. I would prefer swapping something as cash is tight, but I would have to find out what you are looking for -- I may have it. Please indicate if you have manuals, schematics, charts and/or plug-in tube sockets for the respective tube tester.

Kindly, email with details.

Thank you.

Having email problems -- my correct address is:

In article <4koeq0$cv2@newsbf02.news.aol.com> w8jitom@aol.com (W8JI Tom) writes:
>Why are you guys wasting time arguing terms when the problem is with
>someone's concept of RF circuit behavior? This seems like a Mexican Hat
>dance, or a Snake dance around the real issue. It even snakes all over the
>newsgroups in four or five places at once, like that is necessary!

When the parties disagree on the fundamental meanings of the terms
they are using, no useful discussion can take place until those
differences are resolved. When such basic things as voltage are
an area of misunderstanding, what good does it do to talk about
RF circuit behaviors that very much depend on voltages?

As to the discussion spilling over into multiple groups, I don't know
who first crossposted into the antenna group, but the discussion started,
at least for me, in the equipment group in response to an article about
the behavior of excited coax outer conductors serving as RF chokes, and
that's where I have been replying. Since it is not obvious from which
group a given crosspost emanates, of necessity the responses have to be
crossposted as well.

Since it seems of more relevance exclusively in the antenna group at
this juncture, I have been setting the followup line exclusively to that
group in hopes of isolating the thread there. But replies seem to keep
coming back here crossposted yet again into the equipment group. As far
as I can tell, it has been limited to these two groups, and not to four
or five groups as you have said. What other groups have you seen it in?

Someone does seem to have a penchant for changing the title of the
thread promiscuously, and that has the disturbing tendency to scatter
the topic inside the two mentioned newsgroups. Perhaps if whoever is
doing that could leave the title line alone, we might keep the thread
more coherent.

Looks like I have egg on my face, and not just a little egg, either.
<g> After reading Tom's followups, I decided to go back to the books
to see what I could dig up on 1/2 wave verticals.

My apologies Tom, you were correct. If it's shunt fed in the center,
it behaves like two 1/4 waves. It will have a low impedance at the
bottom and a high impedance at the top. BTW, I also found some
interesting information on J-fed 3/4 wave towers, but that's another
story.

The other thing I discovered is that the 1/2 wave shunt-fed vertical
is in no way a "classic example" of anything other than a 1/2 wave
shunt-fed vertical. Can I suggest that we resolve the issues that are
actually relevant to this thread before moving on to areas like this?

Hi Gary,
In article <1996Apr13.222028.26963@ke4zv.atl.ga.us>, gary@ke4zv.atl.ga.us (Gary Coffman) writes:

>There's no way you can get around the fact that current goes to zero
>at the open end of an antenna, Jack. There's no place further for it
>to go, it has to stop there and be reflected

That is true Jack. Current goes to zero.

>So, both antennas have a fixed high impedance at the top that cannot
>be changed. Now applying wave reflection theory, that means that 90
>degrees down from the top will be a current maximum/voltage minimum,
>and hence a low impedance point. Has to be, it's the law. Now 180
>degrees down from the top, wave reflection theory tells us we must
>have another current minimum and voltage maximum, a high impedance,
>have to, there's no choice, it's the law.

Not at all. First we have to define what you call impedance at this moment in time. As this snake wanders around I'm not sure what thee definition of the moment is. At first the structure was shunt fed, now I'm not so sure.

If it is the series impedance, Eznec predicts the following at each point given as a percentage of height on a 1/2 wave freespace resonant conductor grounded at one end: 80%=25 -j647, 65%=123 -j813, 50% 2654 -j229, 35% 385 +j694, 20% 309 +j529.

There is no current maximum at the middle unless the antenna is series base fed. In that case it's an insulated tower, not a grounded one. When fed in the middle it will actually have two current maxima offset from the middle. Don't take my word, it's EZ to model on EZnec.

> So the bottom of a halfwave
>vertical is a high impedance. No matter what it is connected to at the
>bottom, it can't supply current to it because it is at a current
>minimum, is a high impedance source, and practically nil current
>can flow. Has to, it has no choice, it's the law.

It must be a private law, because models and long-hand analysis prove otherwise in the case of a grounded base half wave that isn't series fed at or near the bottom.

>So what? There's nothing, repeat nothing, magic about ground (dirt).
>It's just a poor conductor that happens to be large.

Are we using a very lossy media? I thought it was a ground, as in "the base of the antenna is grounded". If it is a connection to a very lossy

media, define it.

>Not just wrong, but dead wrong. Current will be maximum halfway down
>the 1/2-wave antenna, just as the little diagrams in the antenna
>books show it to be, just like they show current to be minimum at
>top and bottom. Has to, can't do anything else, it's the law.

Not if the bottom is grounded. Unless it isn't really grounded, it's two inches deep in dry pure silica.

>And you have made me very happy I'm on this side (impedance at the
>open end of a resonant halfwave antenna low indeed! chortle, snort)
>I'd like to see Tom's face when he reads all this. :-)

Such childish remarks! Does that stuff really help your technical point Gary? Shame on you, you're smart enough to make a point without remarks like that, aren't you?

If the system isn't defined correctly any analysis will be flawed. Define the system.

Betch'a this is entirely off the topic: I run "Rice Burners" because I can't locate US made toys, I can't afford Motorola (who sneaks in a lot of rice fed stuff anyway!) and if I could afford to buy Motorola I couldn't afford to keep reprogramming it every time I need to do something different in ham radio.

But just let some USA made VHF/UHF radios pop up on the market and I'll trample others getting to the store to buy them!

The ARRL Antenna Book states that a 1/4 wave feedline (or odd multiple) will minimize antenna currents when "the coupling apparatus is grounded at the transmitter." It further states that "if the transmitter has fairly large capacitance to ground, a system of this length will be effectively detuned for the fundamental and all even harmonics when grounded to the transmitter at the coupling apparatus."

Gary, this contradicts most of your claims relating to shield length and ground. It deserves your comments.

Well, since ready-made equipment for your needs is quite hard to find, I would think your message is on topic: you will have to adapt what is available. You could start with a FM car radio and a VHF ham band converter like we use for Amateur TV. With a crystal change and a retuning of the front end, you would just have to pick your signal off the FM detector...

No need to worry or appologize Jack. You're always disagree in a
non-personal and mature way.

The grounded shunt fed 1/2 wave vertical may be a bit tricky to
understand, but it is also good for proving the point about feedline
lengths. If that antenna is modeled (using a program capable of analyzing
currents at close spacings) you'll see something interesting. When
shunt-fed at a point 1/4 wl above earth the tower has very little current
below the shunt feed wire tie-in point!

If I were going to build a system like that I'd use a skirt for a feed
wire.

Anyway, the very example given by someone to discredit well accepted fact
actually confirms the fact someone was attempting to disprove.

Use a 1/4 wl coaxial feeder to a dipole, and the line will have minimum
parallel line currents (as a general rule). Use a 1/2 wl feeder, and the
line length helps bring the problem right home to the hamshack.

KENWOOD TM-214A Expanded RF M/C.

1. Disconnect the power and antenna.
2. Remove the top and bottom cover.
3. Remove all knobs from Front panel.
4. Remove the nut from the mic jack and nut from the channel switch.
5. Remove four screws holding the Front panel.
6. Remove the three screws from the control board.
7. Locate the green jumper wire on the control board.

8. Cut the green jumper and tape the edges to prevent them from shorting.
9. Install chip diode D209 on the control board (Part# MA141A).
10. Reassemble the radio.
11. Reset the microprocessor (Press and hold [MR] while turning on the power).

Hope this help's..... Ray.

Jerry...

There is a factory authorized mod for the FT-8500 noise problem...

Yaesu made the mod on my radio for no charge! If I remember, 1 diode, 1 cap, and 1 resistor.

Contact Yaesu at 310-404-2700. Ask for Kevin Karamanos

It's a valid concern. Alkaline batteries contain a significant
amount of Mercury. I would not be surprised if some of the battery
manufacturers have recycling programs.

At one time radio shack advertised that they would accept
Alkaline batteries for recycling but the store managers
I spoke with knew nothing of the program.

>through electrostatic and dynamic forces.

Hi Tom,

This terminology is not an uncommon means of viewing and analyzing a circuit. In my case, it's the result of thousands of hours of schematic analysis and equipment troubleshooting. Like others in the field, I have found that this language not only provides a perspective unencumbered by particle theory, it is universally understood.

The process of analyzing and troubleshooting equipment at the component level is not too different from the exercise we have been involved with here. In addition, because the audience is diverse and because particle theory is mostly unnecessary to gaining an understanding of the circuit, I chose this particular wording.

Gary also took exception to my use of this terminology, but for less valid reasons than yours. Because his own statements regarding the circuit were (and continue to be) severely flawed, he chose to shift the focus from the ongoing analysis to terms and definitions. Unfortunately, a review of the "correction" to my statements reveals a set of definitions and explanations that could not possibly be applied without bringing the discussion of shield current to an immediate and chaotic halt. That was, of course, the intended result. Readers left without an understanding of the circuit would remain unable to discern fact from fiction, or more to the point, to associate each with its respective author(s).

As a side note, in the many years that I was involved in equipment service, the worst examples of "butchered" equipment came at the hands of two groups; those with inadequate electronics exposure and experience, and electrical engineers. For the latter, it's my opinion that in many cases their professional skills were geared to finer pursuits, and that simply put, the individual was often unable to see the forest for the trees.

I don't mean to demean the engineering profession with this comment, nor do I mean to stereotype all engineers. I have met many engineers who were expert at both design and failure analysis, as well as those who could do neither. Rather, I only mean to say that the skills each of us acquires are usually most effective when applied to their

intended endeavors.

So it goes with terminology and I maintain that the wording I used was appropriate to both the general audience and the analysis. Any attempt to disassemble the inner workings of the circuit at the particle level is not only unnecessary, but potentially destructive to the purpose of the discussion.

It is hoped that you and others will consider my description in the context of the nature of the discussion at hand, and will not take offense. In all honosty, had this thread been an exercise to acquaint readers with the Artificial Ground or shield currents through particle analysis, I would not have bothered to even get involved. Such a discussion would be far too silly and far too useless to be worth anyone's time or effort. ;)

73,
Jack WB3U

Message-ID: <3171861A.587A@mtnweb.com>
Source record: 202749

I am selling the high power version of the Yaesu FT-10. This is the top of the line with the voice memory chip and all. 99 channels, pl encode and decode, dpl, paging functions. If you want more info email me. I paid $305 for it about a month ago, and have hardly used it. I think I may have charged the battery 4 or 5 times. I prefer to sell it to someone locally, but will ship if necessary. I live near Santa Cruz, so anyone in the SF Bay area is pretty local. Asking price is $290/offer.

Josh

Date: 1996-04-14 00:00:00 UTC
From: n9mxt1@aol.com
Message-ID: <4ks3ru$j6r@newsbf02.news.aol.com>
Source record: 202750

Hello,
I am again selling my PK232MBX TNC with the following:

1) PK232MBX TNC "GREAT Condition!"
2) RS232 Cable to run TNC to computer
3) Power Supply 13.8v
4) Empty 8 wire cable for adapting TNC to any radio
5) Manual
6) Software Included
7) Audio plug for adapting to audio output of radio to TNC
8) Extra Cable to run TNC to KENWOOD HF rig if you want it

TNC does RTTY, ASCII, AMTOR, PACTOR, VHF & HF PACKET, and WEFAX capable.

Going price is $200 + shipping
Payment is eithor of two ways......

1) COD = $200 + $10.00 (shipping costs + COD costs) = $210.00
2) Postal Money Order = $200 + $5.00 (shipping) = $205.00

If interested please email me back A.S.A.P. Thanks.... N9MXT1 -
Jeffrey

871. Re: FT736R performance on 70cm

Newsgroup: rec.radio.amateur.equipment

Message-ID: <3171C8F9.2FC9@tiac.net>
Source record: 202752

Hi there. My name is will, and the radio shop I work at has about 25-30 ge MARC-V trunked mobile radios that they want to get rid of. These are all in working condition with a number of mic's and mounting brackets. These radios are GE-STAR trunling format some single system some multi. I do not know if these radios can me made to work talkaround or if they can be moved to the 902-928 mhz amateur band. The asking price is $100 for the multi system and $80 for the single system radios. Quantity discounts can be aranged. This is a cheap way to add extra units to an existing fleet and a great source of parts for any experimenter. Email me or call 617-491-2680 till 10 pm est. tnx, 73, N1PXA

From: Reid Simmons <rsimmons@pop.qtm.net>
Message-ID: <4krh49$rp@news2.qtm.net>
Source record: 202758

Hi Bill;

I know I am late on this thread but I must put in my "two cents".

I have had my Omni VI since they first shipped in the summer of 1992), (yep I am one of the first) and I can whole heartedly say that I LOVE EVERY CUBIC CENIMETER OF IT.

I have been hamming since 1961 and have had a variety of rigs over the years. In the early seventies I went "the way of the Jap rigs" and I can tell you that the fun I had previously enjoyed in Ham Radio declined went away.

The Jap rigs did (and still do) lack engineering quality and true inovation -- i.e. if they can't copy it from us you won't see it in their products.

When I went looking for a new rig in early 1992 Ten Tec had just announced the Omni VI. I decided on the spot that I had to have one. It was the perfect rig -- well thought out (hear me Japs) and not a too many bells and whistles most of which you will never use.

Well when I finally received my Omni VI(there was a waiting period then since demand was so high) I decided that all my Jap stuff had to go "yesterday if not sooner!"

I sold some, gave some away, and since there is not a big market for most Jap stuff, I wound up throwing a lot of it into the trash can!!!

Since I got my Ten Tec Omni VI Ham radio has become FUN again!!!! I have since bought their six meter transverter kit which is also great (better than the kits from Heath) and I can't wait for Ten Tec's next HF offering.

This was my two cents... or was it three!!

884. Help me, IC706 rx pre-amp etc

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-15 00:00:00 UTC
From: Peter Shintani <shintani@tv.sony.co.jp>
Message-ID: <4kunlq$bnl@oskgw.osk.sony.co.jp>
Source record: 202564

Hi Gary and others:
1) I was looking over the schematics of the IC-706 and was shocked to
see that the pre-amp circuit was not discrete but an NEC upc1658.
(I should have realized that for cost and size restraints ICOM
would have to revert to IC's for efficiency) .I looked up the specs
and was shocked to see that the nf was listed as 2.0 whereas
typical FET tr's used in pre-amps are in the sub 0.5 nf range.
I was wondering if this is just my imagination or misunderstanding
but is a front end amp with an nf of 2.0 going to make my
rx noisey in comparison to a discrete implementation with a lower nf ?
(would the affect only be noticeable on 6m or 2m ? but not at hf ?)

2) I was wondering if anyone has figured out how to hot rod the SSB tx per
formance ? For example in a past QST article outlining how to add an RF
speach processor to an IC-726, would a similar mod be easy to add to the 706 ?
I know it is a tight fit, but has anyone thought of adding an RF speech processor?

3) Has anyone tried using an external RF speech processor, the type that
clips the voice at RF and returns it to baseband audio which is then
inputted to the rig's mic jack ? Since the RF processor should raise
the average RF output, can the 706 handle the increase thermal load on
the finals ? Or is this insignificant ?

4) I don't know if it's just my location's poor background noise situation,
which causes the AGC to act un-necessarily, but I would like to know if there
is a simple mod to defeat the AGC or to change the time constants ?

Peter

885. **BIG overhaul to Ham site-->http://www.csz.com/sarrio.html**

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-15 00:00:00 UTC

I've made a number of major changes to my Ham Web site.

1. Ham Club web page development.
2. New Ham opinion page
3. Review unique Grad-N-Go FieldDay type antenna system.
4. Opening the first Ham Purchasing Club.
5. Our site continues with such favorites as the Free on-line classified ads page.
6. The Ham Poll continues... (only Ham Radio survey on the Web).
7. Great Ham Links continues...
8. and our Discount searchable Ham Catalog.
9. I added HTML Level 3, and Java scripting to the site.
10. I've also added an alternative TEXT ONLY option at our browser selecting front door.

Thanks for taking the time to read this message. If you should visit my site, please e-mail me your opinion on its new design and offerings. 73's Ray

Date: Mon, 15 Apr 1996 02:38:40 GMT
Organization: Netcom
Message-ID: <4kscrr$ag6@dfw-ixnews7.ix.netcom.com>

Does anyone have any tips for field programming the JT1000? I have
been told that some of the "software" programmable features can be
performed via the keypad. I have the programming plug and am able to
program the basics(freq, squelch, dpl, etc), but would like to enable
additional features that the radio's are capable of. My dealer can do
this for me, but I am involved in search and rescue and don't want to
be without my units for an extended period.

If anyone can help, an e-mail would be appreciated. Thanks in advance.

James Allan

I have a copy of the service manual for the FT221R but not the owners
manual (unfortunately). I can probably have it copied (if I can talk
my boss into monopolizing the photocopier<g>) it but it would be
quite bulky and might take a bit of time as it is a fair size.

897. Re: Crystal Ordering - How?

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-15 00:00:00 UTC
From: toyboat@freenet.edmonton.ab.ca
Message-ID: <4ksuq1$dhr@news.sas.ab.ca>
Source record: 202673

-- Could someone kindly instruct me on how to order amateur radio crystals
for an old homebrew crystal-controlled CW tube transmitter?

The rig in question runs about 30W to the final (6L6), is two-stage,
and has a B+ of 350VDC. The oscillator (6C4) is a Pierce circuit.

I have brochures from two crystal makers, but have never ordered
before. I know that I want an FT-243 mount prferably and that
they must be 80m or 40m crystals of Fundamental frequency. The
rest of the information I am uncertain of.

I basically want crystals that won't be damaged by higher drive
levels that these simpler transmitters used. The description
of these crystals must have been simple in the 40's, 50's, and
60's. Now, however, the info for ordering is:
1) Crystal freq.?
2) Holder type?
3) Tolerance (parts per million)?
4) Series/parallel resonance?
5) Crystal load capacity?
6) Oven or non-oven?

Please e-mail me if you can assist me with a description. If you can
simplify what seems complex, I thank you.

Shane

898. Mods for Yaesu FT-5100, CrossBand Repeating??

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-15 00:00:00 UTC
From: dd650@cleveland.Freenet.Edu
Message-ID: <4kt4us$1tk@madeline.INS.CWRU.Edu>
Source record: 202674

I was surprised to find that the 5100 does not have the same scanning range as the 51r HTs. I would really like to be a ble to scan at least to 470 mhz. Are there any modifications that can be made. Also, I have read the manual several times and am sure I haven't overlooked anything, but is there an undocumented way to get the 5100 to do a cross band repeat, similar to the way the Yaesu 51r does?

Thanks!

> 3) Tolerance (parts per million)? 0.05% Minimum
> 4) Series/parallel resonance? Parallel
> 5) Crystal load capacity? 32pf.
> 6) Oven or non-oven? Non-Oven

Remember that if the rig doubles on a particular band then the operating
frequency of the rig will twice the crystal freq. EG.. if you want to operate
on 20 meters at 14.030Mhz then you will need a crystal frequency of 7.015Mhz.

Good luck es 73's Dick K8WHA

Jack is absolutely right here about the coaxial transmission line. The mathematics of the situation requires the current to be equal and opposite on the inner conductor and inside of the outer conductor. At the load end some sort of impedance is connected between these two points. Part of this impedance could be a path which includes the outside of the coax. This does not upset any fundamental laws or require any other current sources. This can be difficult to visualize, but that doesn't mean we should change electromagnetic theory.

907. FT-736R vs TS-790 vs IC-820H

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-15 00:00:00 UTC
From: Joseph M Zawodny <j.m.zawodny@larc.nasa.gov>
Message-ID: <317275CE.446B@larc.nasa.gov>
Source record: 202683

Hello,

I am considering one of the following for a satellite, packet,
and SSB contesting: FT-736R, TS-790, or IC-820H. Assume that I am only
interested in the 2m and 70cm bands so I don't care about plug in extras
such as additional bands and the like. What are the pro's and cons for
each of these rigs? I will be using these with computer control, what
information can I get FROM the radio via the computer interface? Since
the 820 is rather new, how does the computer interface differ from the
IC-970? Will a program that was designed for use with the IC-970 work
with the IC-820H? I read the QST review of the 820H, but found that it
did not address many of the items mentioned above.

TIA 4 the info.

909. Good Mic for FT 900?

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-15 00:00:00 UTC
From: "Gregory J. Buhyoff" <buhyoff@vt.edu>
Message-ID: <4ktuvv$f48@solaris.cc.vt.edu>
Source record: 202685

I am using a FT 900 and it is a good performing radio. However, the stock hand mic that comes with the radio can probably be improved. I am using the FSP with an offset of +150 and the mic switched to the number 2 position. This is still not providing the audio I would like for DX'ing (I am not trying to sound "natural" -- I am trying to communicate during marginal conditions). I am wondering if anyone out there has found a really good FT 900/mic combination? In addition how did you get around the mic connector "problem"? I know Yaesu makes a converter cable but it terminates in female 8-pin connector rather than a male 8-pin. I realize this is not big deal and I can make up the necessary conversions. However, I am interested to find out if there are some bright ideas that I have not considered. So, again, your thoughts on great microphones for the FT 900.

Thanks and please respond to me via my email address Buhyoff@vt.edu

73, Greg KN4FR

ea4abb@linux.ea4abb.ampr.ORG (Roberto Munoz (EA4ABB)) writes:
>Someone wants to sell me the IC-970 from ICOM.
>I need a radio to go on satellites, but this radio is it good ??
>Perhaps the FT-736 or TS-790 are better ???

The IC-970 is an *excellent* radio for satellite operation, but it
is usually so expensive that it isn't the most cost effective choice.
If you can get it at a good price (no more than a *new* FT-736R),
however, go for it.

The FT-736R has been the workhorse radio for satellite operation
for a number of years. The design is old, but it is sound, and
the price is reasonable.

The TS-790A should be avoided for satellite use. It has *serious*
design flaws for such usage. Not recomended. It can be Ok for
light duty terrestrial use.

The IC-275H/IC-475H pair offers another *excellent* route to
satellite operation, but again the pair adds up to considerable
money.

The IC-820H may be a suitable candidate as a satellite radio, but
I don't have any first hand experience with it yet, so I can't say
that with assurance. It looks good on paper.

912. ICOM IC-706 75/80-mtr problem

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-15 00:00:00 UTC
From: Carl Estey <carl.estey@HBC.Honeywell.com>
Message-ID: <31727A8B.622C@HBC.Honeywell.com>
Source record: 202688

Has anyone noticed reduced RF output on any one band of the IC-706, even into a 50-ohm dummy load? I get only 50 watts out on 75/80-meters and no ALC action. All other bands are fine. The reduced output is independent of the load (antennas and dummy loads all work the same for me on 75-meters - reduced output).

Any suggestions?

73, Carl

Can anyone help,
I have a Yaesu FT10R (b1) and wonder if anyone has any
mods for the radio?.

If you all ready have a FT10 with extended RX could you please

1. Remove the battery pack.
2. Remove the "Ni-cad" sticker (The sticker will peel off with any
damage to itself.)
3. Remove the two screws which secure the keypad.
4. The keypad will now be released from the radio.
5. You will now be able to see the green PCB and Solder pads (H,I,J)
and SMT Chips/Mounts (k,L,M,U,V).
6. Grab a pen and paper and take a note of the position of all the
pads ETC.

Eg. l,M,V are Chiped and Pads H,I are soldered.

7. Reassemble the radio.
8. Please E-mail me DIRECT with your findings..
9. Give yourself a big pat on the back..!! and have a cup of coffee.

Please Remember to E-Mail me DIRECT...

Thanks Ray..

This message describes the rec.radio.amateur.*, rec.radio.cb,
rec.radio.info, and rec.radio.swap newsgroups, as well as their Internet
mailing list counterparts and complements. It is intended to serve as a
guide for the new reader on what to find where. Questions and comments may
be directed to the author, Jay Maynard, K5ZC, by Internet electronic mail at
jmaynard@admin5.hsc.uth.tmc.edu. This message was last changed on 31 October
1994 to add the discussion of non-Usenet mailing lists and streamline most
of the history discussion, and to change the moderator information for
rec.radio.info.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list
for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions
were held on the mailing list, and sent to the mailboxes of those who had
signed up for it. When the Usenet software was created, and net news as we
now know it was developed, a newsgroup was created for hams: net.ham-radio.
The mailing list and the newsgroup were gatewayed together, eventually.

Over the years, as the net grew, the volume of discussion became
progressively higher. First one by one, and then as part of two
reorganizations, what was once one group became many. In the process,
developments elsewhere on the net were reflected in the groups as they were
created, most notably the change to place all of the ham radio groups in one
hierarchy.

The collection of newsgroups continues to grow as more people join the net,
and as more topics of discussion gain volume, I expect to see more groups be
created as well. This follows what is happening on the rest of the net.

Nearly all of the radio newsgroups have corresponding mailing lists, the
notable exception being rec.radio.swap. There are also a few mailing lists
that don't have newsgroups.

The Current Groups
==================

It's important to post messages to the group that's appropriate for them,
and not to the groups that aren't. The whole idea of having different
```

newsgroups is so that folks who aren't interested in, say, homebrewing, don't have to wade through messages about homebrewing on the way to read about Field Day. Posting appropriately is just good etiquette.

The rec.radio.amateur.misc group is the catchall. It is what rec.ham-radio was renamed to during the first major reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, was removed on September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there. To answer a frequently asked question: No, there is no mailing list that goes along with this group. If you can't read Usenet news directly, you're out of luck.

The group rec.radio.amateur.policy was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate - it's now legal to order a pizza on the autopatch, if you're not in the pizza business - as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The group rec.radio.cb is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently David Dodell, WB7TPY. The email address for submissions to the group is rec-radio-info@stat.com. Inquires and other administrivia should be directed to rec-radio-info-request@stat.com. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups rec.radio.amateur.antenna, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas, commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

Mailing Lists

In addition to the mailing lists that mirror the Usenet newsgroups, there also are a few that stand alone. These cover specific areas of ham radio, and discussion is focused on just those areas.

The cq-contest mailing list is for discussions of contesting in ham radio. To join, send email with the word "subscribe" on a line by itself to cq-contest-request@tgv.com.

The DX mailing list covers the finer points of DXing. This one is also joined by mailing "subscribe" on a line by itself, this time to

dx-request@unbc.edu.

There's also a VHF mailing list, for VHF operators of the weak signal persuasion. You can join this one be sending "subscribe vhf" on a line by itself to vhf-request@w6yx.stanford.edu.

All of the following mailing lists are sponsored to the Boston Amateur Radio Club, as well as some others of local interest. Thanks to N1IST for the information.

qrp-l: This is the qrp mailing list, previously maintained by Bruce Walker at Think.com. It is for discussions about the design, construction, and use of qrp (low power) radios and related equipment.
arrl-ve-list: This is a one-way list, run by Bart Jahnke of the ARRL VEC, for announcements to VEs and VE teams.
w1aw-list: ARRL bulletins, news, and information
newsline-list: Redistribution of Amateur Radio Newsline
letter-list: Redistribution of the ARRL Letter
fox-list: Fox hunting and Radio Direction Finding
fieldorg-l: ARRL field organization discussions
ham-tech: Technical discussions and questions about Amateur Radio
arrl-exam-list: amateur radio license examinations scheduled in the US and in some foreign areas.

To sign up or inquire about these lists, send mail to listserv@netcom.com with the following in the body (subject is ignored) of the message.
<listname> is the name of the list to subscribe to.
To subscribe: subscribe <listname>
To unsubscribe: unsubscribe <listname>
For more information: help
To post (to the two-way lists), send your message to <listname>@netcom.com

Please do NOT send subscription requests to the mailing lists themselves; that doesn't work very often, and is very annoying to those on the list. Also, please keep your electronic mail address current with any mailing lists you subscribe to, as dealing with returned email is a nuisance for the person maintaining the mailing list.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while

still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

If you don't want other bands then stay a way from the Yaesu 736 - my experience is they have poor receivers. They overload easily with strong ssb signals. The Kenwood 790 has a better receiver and you can monitor both bands at the same time - you can NOT do that with the 736. I don't know much amout the Icom 820. Kenwood and Yaesu are both overdue for new multimode vhf/uhf rigs. Good luck. --- Steve N9ROU

Message-ID: <HpLuvCApoqcxEw+H@golfmike.demon.co.uk>
Source record: 202700

I have a Yaesu FT736R fitted with the FTS-8 tone squelch unit.

I want to mod the radio so it can switch on other equipment
(such as a tape recorder) when the FTS-8 receives a valid tone,
and opens the squelch.

Someone told me to connect a wire to the front panel 'BUSY'
light, and us a transistor to switch a relay. This is almost what
I want, but the busy light comes on even when the FTS-8 keeps
the squelch closed.

Any ideas?

It appears that the "Artifical Ground" thread may be about over.
Nevertheless, I wanted to repond to this particular post because it
describes several misconceptions regarding currents in and around
the typical HF transmitter chassis. Sorry I didn't follow up sooner;
it didn't appear on my news server until earlier today.

gary@ke4zv.atl.ga.us (Gary Coffman) wrote:

>leaked a lot of RF into the shack (if it did, I wouldn't *care*
>if RF also came back down the feedline because I'd already have
>a "hot" shack).

Leakage currents around the cabinet generally aren't detectable by
touch. Even significant leakage won't usually cause the symptoms
associated with a "hot" shack. The latter is the result of high RF
voltage, not current. Also, in terms of radiation, the size of the
cabinet is only a small fraction of a wavelength. It would require
an extraordinary amount of current to create notable symptoms.

>So I'd suggest that any leakage either way is going to be minute,
>which implies that the pathway through the shielding is a very high
>impedance.

I don't know what the actual impedance is, but I don't believe it's
very high. It might be a few hundred ohms, but it certainly isn't
thousands of ohms. Like I said before, the evidence of this is that
the appearance of voltage on the cabinet (such as results from common
mode feedline currents) often causes the transmitter to malfunction.
Sometimes this occurs long before the operator is even able to
physically detect the voltage, indicating that even moderate levels of
RF voltage on the cabinet can cause disruptive currents to flow into
the transmitter.

>I deleted the rest of your argument because it is premised on the
>outside of the chassis being at the RF potential of the inside of
>the chassis, which it isn't. If it were, you could take a transmitter

>up in a balloon and draw arcs from either the antenna or the chassis
>since there's no nearby Earth to unbalance it and make the outside of
>the chassis cold. But you can't. The chassis is still cold up there
>far from Earth too.

No, it's not. Measurement from any third point will show the voltage
on the chassis is nearly equal to the voltage at the feedpoint of the
antenna.

>But you *can* draw an arc from the end of *either* leg of a dipole
>fed by that transmitter,

Of course you can. There's an impedance transformation along each leg
that steps the voltage up at the end. Attach a 1/4 wave wire to the
chassis and the same thing will happen.

>showing that both the inner and the *inside* of the outer of the coax
>are hot.

None of this disproves the existence of a current path between the
inner chassis and the cabinet.

> before you start???

No, you're right, I'm guessing. Let me re-phrase:

If it could be re-tuned to a higher frequency, it would *probably* be a
very poor performer in the 900 MHz amateur band.

It's not that I'm giving up before I start, but more a matter of what the
author of the original post was after. It sounded to me like he wanted a
easy way to have a scanner or a 900MHz HT, not necessarily a learning
experience. If he was after knowledge of radios, microprocressors, or
mobile telecommunications, then this would be the project to do, as you
have done.

-snip-
> Of course there is a PLL controlled by a micro. Any yes, you will have to

>
> ..Peter
>
> PS, yes, I have done this.

What make and model have you done this to? I'm actually curious as to what
processor and periphials they used.

I think if you stick around this newsgroup for a while, you'll see quite a
few posts about "What can I do with this cell phone?". Not saying anything
about "jclind@sentex.net", but alot of them are people with a piece of

equipment they don't have the heart to throw away, not necessarily people
that want to learn how a mobile phone works.

I must admit sounding pesimistic about this, but I see it as being practical. :)

Several manufacturers (sp?) still offer there units to the government or agents there-of (read Contractors, Procurement Personel, Vendors, etc).

There are many reasons for this (in addition to the ability to LAWFULLY monitor Cell Freqs. i.e. with a warrant.)

Military Contractors do, every once in a while, try to save the Gov. money by using off-the-shelf parts (or units) in a system design. Why go through the process of designing and building a reciever to cover, say, 30 MHz to about 2 GHz, if that RX is availible for a couple K. This type of RX could be used as a monitor RX for a veriety of things. Could be the heart of an ELINT Sys., could just monitor many different transmitters operating across bands close to the cell freqs.

I use an R7000 at home, and an R7000, R7100 and two R9000's at work. But none of these nice radios can compare to the combination of an AN/WLR-1G, AN/WLR-11, a HP 8365B, and the odd AN/SLQ-32V3. With this combo I can monitor ANY frequency from 15 KHz to about 26 GHz. But I have NEVER intintionally (sp?) listened in on a Cell Call.

And sometimes you may need to be able to detect a given Freq even if you only use that freq as an I.F. and are up- or down-converting to it.

Well I guess there are no answers here only a bit of rambling,

Clear Skys and Low Noise.

QRP is not the best way to enter the hobby. After you've got some experience under your belt, you stand a much better chance of enjoying QRP. I would recommend at least 25 watts. You can pick up some nice buys on 10 meter rigs, used, at hamfests. I've bought two so far, and paid $100 each. Both worked. This time in the solar cycle, 10 meters tends to be fairly dead, so you may want to opt for a lower band. I like the looks of the Scout 555 from Ten Tec, but at $550, it's a little steep, but you get 50 watts output, more than enough to get started. (My first rig was a heathkit DX 60 transmitter, one crystal for 21.150 and about 60-70 watts out. Worked quite nice.)

Another option is an older used rig. Rigs with tube finals can be had fairly cheap. I've still got the Kenwood TS-520 I bought new back in 1979. Very maintainable rig, no special micros that get hard to replace after time. These show up at hamfests for about $250 to $350, and will provide more than 100 watts CW.

If you go looking for used gear, find an older ham to help out. There is no substitute for having owned a rig for several years when looking at used gear.

Just my $0.02

I'm looking for a 2meter only OR a dual band 2meter/70cm mobile unit
for a boat that is watertight "built like a marine spec radio", OR
a housing of some sort for a regular mobile unit. Also what kind
of antenna system should I use for it as well ? The boat will only be used
on lakes and maybe a few rivers as well. It has an antenna for the AM/FM
radio in it the goes through the bottom of the hull into the water. Is
this the kind of setup I should use as well ? Any help will be
apprieciated. If you can E-mail me OR if you think anybody else might
be interested in the info just post it here .

Thanks,

Tom Simpson KF4GKW

From: JSE@delphi.com
Message-ID: <4kv57u$h39@news2.delphi.com>
Source record: 202582

.....

I've been away from electronics since I built my first ham station
in the days of Ye Olde Vacuum Tubes. All electronics were easy to
work on when innards were just tubes and wiring.

Now I'm trying to make a few simple repairs inside a handheld
transceiver, and I find that even the tiniest 10 watt tip on
my soldering iron is much too big to heat a tight connection
on the PC board without also heating the connections to the left
and right.

Are special soldering irons available with teeny-tiny tips?
Or do I file down my smallest tip to make it fit into the
necessary spaces?

Thanks for advice or suggestions to the ol' geezer!

From: Barry Brazier <barryb@deakin.edu.au>
Message-ID: <4kvbkt$ktt@sol.ccs.deakin.edu.au>
Source record: 202586

I am buying a yacht in the US to sail back to Australia and to save money I was hoping that I could buy a US transever that fitted Australian marine specs. But after talking to the Australian agency it seams that in Australian waters it is not just enough to satify the specs. Each australian boats has to use Hf radios which is "type approved" This mean it must have a stamp on the back detailing AUS approval.They claim that Oz specifications for marine use are different to other counties There's a $10,000 fine for using another radio on marine bands out here.
One option is to buy a second hand marine SSB in the States for use outside and keep my old australian HF for use in australian waters
My old stringray is a crystal tuned SSB.HF with the following freqencies:
2182.,4125,6215,,2524,4483,2201 and radnar chanel 402 (4426/4134).The first three are distress/calling frequ. the next two are yacht race and recreation frequ. and the 2201 and 402 are working ship to shore frequ.s

Are any of these used in US and Pacific waters (I know 2182 is used universally for distress). I can add three more frequ. What would you suggest for some international application (a 6meg radnar chanel?)

Re: crossband repeat. Set up the 2 meter and 440 frequencies that you desire (these can be repeater pairs), set the radio to low power on both bands because of the high duty cycle in repeater type operations, and shut the radio off. While pressing the RPT button, turn the radio on and it will bew in cross band repeat. I recommend getting the PL decoder if you use this function very often as it will help prevent inadvertant keyups.

How many times do I have to read messages from hams that send a
"Thank You" addressed to ALL. When one seeks help and
someone takes the time to respond, the least the receiver of
help can do is send a simple individual reply for thanks. After
all-the respondents to this call for help responded one by one.
I have received up to 75 messages in a call for help and sent
individual thanks to each. It was very time consuming, but it
was the right thing to do.

Would you at your wedding, if you were the groom, get up at the
end of the reception and yell out, "Gee, Thanks everyone for the
gifts?"
If you are a T Y P I C A L ham--absolutely.

It is unlikely you will respond to this if you did not even bother to
respond to someone who H E L P E D you.

: (TCP/IP)

Carl, I have no ALC action on either 10 or 6 M, but power output is about 90 watts on all HF bands and 6M. In my case, I figured that the overall gain was just pooping out as frequency rose, and there was no excess left to result in ALC action. There were a lot of posts back around Dec-Jan about lack of mike gain and ALC action, and I at first thought I was another victim, but then I found that I had been doing my testing on 10M. When I tried 75, there was plenty of ALC.

I don't think that this helps you a bit. Just my 2 cents.

Joe,

I bought the Ic-820H to use for Satellite work and had a lot of problems with
the interfaces to control the radio's freq., mode, etc. The support from Icom
was not any help. I worked with it for 60 days and finally traded it in on a
new TS-790. I was up and running with full computer control of the radio,
antenna tracking, and Packet TNC in less than a day. I looked at the
FT-736R
but never tried it out. The TS-790 is the oldest of the group, but it does the
job as advertised.

Source record: 202604

I use a Yaesu FRB 757 relay to switch my Heath SB201. It wires into the ACC socket to get 12vdc and gnd and then wires to amp jack on amp from relay module.
706 manual has pin out info on page 6 . Pin 2 gnd on relay module pin 8 13.8vdc to relay module. DO NOT WIRE AMP DIRECTLY TO 706. AES Orlando has more info if you call them. I would suggest you confirm this with either AES or ICOM (Gary Fiber)

Don't be too sure. Back in the 1950s, even ordinary TV sets cost around
$700; that's several thousand in 1990s dollars. Even today, lots and lots
of people fork over $2k - $3K for big screen TVs. I even saw an 80 inch
set for over $8000 (awe inspiring experience!). Never underestimate the
value people place on entertainment.

Universal Radio M-8000v5 Communications Terminal/Decoder
for serious HF, VHF/UHF monitoring!

Provides decoding and video output to VGA monitor using
it's own, internal processor! No computer required.

The decoder includes the following capabilities:

Morse Code (CW), Baudot, RTTY, ASCII, Packet, PACTOR, Simplex
Telex Over Radio (SITOR), simplex and duplex ARQ and FEC codes,
PICCOLO code, ACARS, POSAG and GOLAY pager codes, and
Facsimile (FAX) images, and WFAX (Weather FAX)!

Includes VGA Color monitor port, printer port, AUX port,
and two audio source inputs!

This is the latest version currently sold by Universal
Radio! List price: $1,499.00, Discounted at: $1,349.00

I recently lost my job and need some fast cash, will sacrafice
for only: $800.00

Has ANYBODY ever thought of checking with the manufacturer before posting here??
There are 14 different manuals and supplements for the MCX100 series (not
counting the user's guides in three different languages). The exact model
number and option features of the radio will determine which manuals your
friend will need. Motorola even has a toll-free number *1-800-422-4210*
for him to call to obtain this information and place an order, usually
shipped same day!

With so much talk about skin effect every where I have never seen
a figure being quoted. I firmly believe some figures will put
discussions and understandings in perspective. So here it goes:

THE SKIN DEPTH AT 100 MHZ IS 0.66 uM (MICRON)

The variations due to different material is within an order of
magnitude. If my memory failed me please quote the correct figure.
I think the number is so incredible that everyone should know.

On some previous posts RF current within the coaxial transmission line
and outside the shield were discussed. The discussion centered on the
effect of line length, particularly at 1/4 wave length and 1/2 wave
length. Doesn't the difference in velocity factors causes the current
maximum/minimum to occur at different location? For RF current within
the coaxial line the V.F. is 66% (or some other number.) For RF
current on the outside shield, due to the skin effect, the entire
cable might just as well as a solid conductor, for which the V.F.
is around 95%. Wouldn't this effect make any difference?

>> Any info would be helpful. Thanks!

>It is an old AM/CW rig running about 120-watts using 6146's. Very
>large and heavy. Built like a tank.

Let me elaborate a little (I used to own one):

Johnson Viking II: 160-80-40-20-15-11-10 meters
crystal-controlled (external VFO required)
180 W. DC input on CW
140 W. DC input on AM
2-6146s in the final
2-807s in push-pull in the modulator
cathode-keying of buffer stage
Pi-network output circuit including
rotary inductor

Very large, very heavy. Has multiple crystal sockets with a
selector switch if you haven't got a VFO. Occasionally exhibits
"chirp" on CW on the higher bands unless the oscillator is detuned
slightly (to reduce the effect of the buffer load varying as it's
keyed). AM is full plate modulation, good quality audio; works
very nicely with a D-104 mike.

Hope this helps.

73,

Paul, K4MSG

P.S. This transmitter is early-mid 1950s technology, BTW.

I have for sale my Yaesu FT-530 dual band HT and accompanying accessories. I bought the rig about a month ago, and now decided that I need to get a higher powered base unit. The HT is in PERFECT, like new condition as it has had about 5 hours of use total. I paid the following prices for the unit (new):

(1) Yaesu FT-530 $329
(2) Service Manual $ 20
(3) MH-29 Display Spkr Mic $100
(4) CSC-56 Soft Carry Case $ 23
(5) E-DC-5 Cigarette Adapter $ 26
==========
Total: $498

Considering that the equipment is essentially new, Ill sell the package to the first offer of $399. Ill pay fed-ex shipping overnight to anyone in the US. If you think that this is an unfair price, let me know and we can discuss it.

Thanks,
Ravi Hariprasad

>Anybody have any information on how the various coils are wound or
>where to get a copy of a manual?
>Trying to dip,
>galen, KF0YJ

Straining the brain, I seem to recall that dipper uses the Hartley
circuit. So the third wire connection is to a tap near one end of
the coil for feedback excitation. Memory could be faulty, but I
also recall that the highest frequency "coil" is just a loop of
heavy wire formed from a piece of wire about 6 inches long and
plugged into only the two outside pins of the socket. Feedback
in that case must be by circuit strays. I had one of these many
years ago, but sold it and bought a solid state version, a Heath,
a long time ago.

Sport Headphones That Work!

Listening to music while you running used to be impossible. Walkman style ear buds fall out or misalign while jogging or running. Even when properly placed, ear buds don't eliminate road noise and wind. Cranking up the sound to compensate for noise is dangerous.

Radio Partners builds custom ear molds to fit only in your ears. They then use Sony's state of the art Turbo ear buds as speakers. Together you have headphones that block wind/road noise and sound great, even on long runs! They don't dislodge when the wires are pulled.

In article <4kv57u$h39@news2.delphi.com>, JSE@delphi.com says:

>I've been away from electronics since I built my first ham station
>in the days of Ye Olde Vacuum Tubes. All electronics were easy to
>work on when innards were just tubes and wiring.
>
>Now I'm trying to make a few simple repairs inside a handheld
>transceiver, and I find that even the tiniest 10 watt tip on
>my soldering iron is much too big to heat a tight connection
>on the PC board without also heating the connections to the left
>and right.

This is not necessarily a problem. During manufacture, the whole board went through a soldering machine which melted every connection at once. The element that needs to be controlled precisely is the solder, not so much the heat. If you shake or wipe all loose solder off the tip of the soldering iron, it won't carry enough solder into the workspace to cause bridges. Do get some fine diameter solder though so you can apply tiny amounts under control. Paste (rosin, *not* acid) flux is also very useful to help the solder flow where it's needed in SMD work.

>
>Are special soldering irons available with teeny-tiny tips?
>Or do I file down my smallest tip to make it fit into the
>necessary spaces?

What I use for general fine soldering is a Weller SP-23 (the ordinary pencil-type iron) with a custom tip made of copper wire. Unscrew the tip and put in a #10-32 pan-head screw, then wrap the wire under the screw and tighten it. Bend the wire so it points forward and cut it about 1" long. AWG #10 or #12 wire is best all around, finer sizes won't conduct much heat but can be used on the very tiny SMD "chip" parts.

>for my Viking II ....

Hi Grant,

Perhaps you've never done an A-B test between a tube hi-fi amp and one using transistors? Whether it's due to the tone controls, the softer clipping of tubes or whatever, there is a distinct difference in the quality of the sound.

On the other hand, the benefit of tubes in ham gear is much less tangible. Given the choice between keeping an old Viking II on the air or continuing to enjoy high quality audio, I know what my decision would be. There are cheaper ways to heat a hamshack. ;)

kendall@vt.edu (Gary F. Kendall) shared the following priceless pearls
of wisdom:

>Does anyone know of a possible source for this battery pack?

Try Ross Distributing in Preston ID. 208/852-0830 I got one for my
2600 about two years ago and seems to me they were about $25 apiece.

Some words of supposed wisdom -- Ross isn't the cheapest in the
country, but always fair and seems to always have what I need. Use
the Rayovac rechargeable alkalines in the battery pack. I'm getting
between 50 and 75 charges out of a set before they go away (they don't
self-discharge like nicads and they have almost the same capacity as a
regular alkaline).

Tell the Ross folks they need to be on the 'net to pick up things like
this -- if I didn't happen to casually spot this, they would have lost
a sale.

Tom--
Seems to me to be much ado about nothing! Before I retired, it was common in my company to have sales folks come in and complain about article in trade journal extolling the virtues of a new system just installed from Timbuctu to Swaziland by XYZ Corp. The article covered all of the technical issues involved and how XYZ solved them with their new Slopbucket radio system. What's different? Nothing that I can see if you regard QST as a trade journal. For Svetlana I would assume that's the view. I would chide those who complain and suggest they submit an article. It's great advertising. I'm sure QST would welcome similar inputs from Eimac or whoever. Every construction article (or most at least) have and ad in the notes telling you where to get parts (or EPROMS programmed by Ole Joe's Widget Shop) etc. Again, what's the difference - none in my mind. I think it's neat that someone is still making tubes for all of those 811A sockets -- RCA sure as hell ain't. If Svetlana can make a quality product for less, then power (pardon the pun) to them.
A tempest in a teapot!

>I'm looking for a 2meter only OR a dual band 2meter/70cm mobile unit
>for a boat that is watertight "built like a marine spec radio", OR
>a housing of some sort for a regular mobile unit.

Hmmm. That's a pretty tall order considering most marine radios aren't
built 'watertight "built like a marine spec radio"'. You might have
more luck finding a housing for a standard mobile radio. Though
heat disipation might be a problem.

>Also what kind
>of antenna system should I use for it as well ? The boat will only be used
>on lakes and maybe a few rivers as well. It has an antenna for the AM/FM
>radio in it the goes through the bottom of the hull into the water. Is
>this the kind of setup I should use as well ? Any help will be
>apprieciated. If you can E-mail me OR if you think anybody else might
>be interested in the info just post it here .

I don't really understand what the AM?FM antenna is doing, but I'll tell
you about my experince with a marine antenna. I have a sail boat
with a marine VHF radio (frequencies around 156 MHz). The antenna
for the radio is a base loaded 5/8 wave stainless steel whip. About 3 db,
these whips are used mostly on sailboats where angle of heel is a factor.

I called the maker (Metz) and asked them how it would work on 2 meter
freqs, they said the antenna is so broad banded, it should work fine.
When I had a chance to borrow a friends SWR meter I checked and sure
enough, about 1.5:1 SWR. Good enough!

So that's one option for you, a 3db stainless whip that can double as your
marine VHF antenna. You can get these from West Marine for $32.

This is the closest group I could find to field these questions to.

My grandfather gave me the radio listed in the subject line. It was made by the National Company of Malden, Mass. circa. 1930-40 or so would be my guess. Does anyone know the approximate value of such an item. (I do not want to sell it; I want to know if it should be insured and if so, for how much. I very much enjoy listening to DX on it.) Also, would there be any way to get a copy of a manual. Fortunately, granddad kept many tubes around for it which he also gave me.

Serious replies to aford@wam.umd.edu would be greatly appreciated.

Thanks,

Without the duplexer, I got less than 3db degradation. Of course, this will
be different for every model. Some units may not run at all or will self-
destruct. But SOME will work without modification!

>It's not that I'm giving up before I start, but more a matter of what the
>author of the original post was after. It sounded to me like he wanted a

You might be quite right about that... It is not a quickie project, to be sure!

>> But you can salvage many subroutines from the old eprom!
>
>You can't universally assume that one can do this. Let's see you get that
>data out of a OTP part with the security fuse blown!

Every model I played with had a micro and then a separate eprom for the
code storage. The eproms were large, typically 1 mb and sometimes 2 mb
parts, which explains why they are outside the mpu (I know of no micros
with that much internal code space... the die would have to be HUGE).

There are many levels to the protocol, plus the routines for the display,
added to the fact that most every manufacturer uses a high level language
for code development (rather than assembler), that account for the large
amount of space required.

Yes, the security in micros is a pain to bypass. If you are determined, there
are tricks for most processors, although it is easier usually to find a company
that will do it for you (see ad in Nuts & Volts).

>What make and model have you done this to? I'm actually curious as to what
>processor and periphials they used.

I played with a Technophone (Hitachi CPU and 27C010 eprom, don't remember
the model # off hand but it was a metal-cased handheld) and also a Motorola
"brick" 9500XL (surprise... it had a Motorola CPU. I don't remember the exact
variant of the 68K but it had lots of on-board peripherals and did most serious

peripheral communications through high speed serial lines. Also had a 1 meg eprom).

The technophone had a 93C46 eeprom for subscriber data and a prom using only one of its 8 bit width for ESN storage. The Motorola used eeprom in the micro for both data, making it harder to directly change it without program intervention. (the easy way of course was to substitute a new eprom one at a time to output to ports and capture on a logic analyzer the stored data then reprogram it. This was my only phone so I was very careful and got the correct data back by the end of the evening. It was a rather expensive unit when I bought it!).

I still have both CPU databooks that I collected, plus the listings (somewhere-I moved since doing all this) but I think these companies would be very pissed at me if I gave them away or divulged much detailed info.

The peripherals for the display and the hardware for the keypads were unremarkable and done as you would expect. The synthesizer and its programming I never did fully comprehend in either unit, although I was able to find data values that produced out-of-band outputs. I did much more toying with the Technophone as I didn't need to be able to use it afterwards.

>
>I think if you stick around this newsgroup for a while, you'll see quite a
>few posts about "What can I do with this cell phone?". Not saying anything
>about "jclind@sentex.net", but alot of them are people with a piece of
>equipment they don't have the heart to throw away, not necessarily people
>that want to learn how a mobile phone works.
>
>I must admit sounding pesimistic about this, but I see it as being practical. :)

I know, it does seem like a waste to chuck so much technology. I was hopeful that there would be hackers playing with the most popular units and figuring out how to do useful things, and sharing this info.

Instead, all we got were crackers only interested in defrauding cell companies and inconvieniencing customers with cloning.

You're probably right in the long run... engineering is valued too little in this country for there to be a big enough engineer population for cellular-to-ham conversions to be a practical reality.

..Peter

>AES or ICOM (Gary Fiber)
>
>John WA4BMG

Be careful because the Yaesu relay may even exceeed the 706's ratings. 20 mA is the maximum current and no voltage is given.

What is the current of the Yaesu relay?

>73, Greg KN4FR

Hi Greg, I am using both the Heil ProSet with HC-4 cartridge and the
Yaesu MD-1C8 desk mike with my FT900. Both work very well with the
rig. To use the desk mike I bought an adapter cable from HRO. The
ProSet comes with your choice of adapters for different rigs. The
Heil/HC-4 combination sounds like what you may be interested in. Lots
of punch for these marginal times.

Hi Al,

That was discussed during an earlier part of the "MFJ Artifical
Ground" thread. For purposes of calculating the length of the outer
shield, 95% will probably come close. Velocity factor inside the coax
obviously prevents the same length of cable from acting as a half
wavelength internally and externally simultaneously.

Of course, the alternative to all this is to use a balun. If the
antenna will be resonant, the coaxial-coil type that Tom (W8JI) often
recommends will do an excellent job.

>> get to the outside of the connector shell, or the outside of the
>> chassis. The thickness of those parts is several skin depths, so
>> their insides and outsides are isolated from each other.

The insides and outsides are only isolated if there is a equal and
opposite current involved. Without equal and opposite currents, even VHF
current can flow right through a chassis to the outside. All shields
depend on this effect.

Inside and outside are bad terms to use. I like the surface and interior
better! While current doesn't flow through the interior, the voltage is
the same on each side of the wall. And the outside is a continious path in
a three dimensional world. The only thing that keeps the current inside a
coaxial cable is the equal and opposite currents, the skin depth "allows"
it to happen.

>With so much talk about skin effect every where I have never seen
>a figure being quoted. I firmly believe some figures will put
>discussions and understandings in perspective. So here it goes:
>
> THE SKIN DEPTH AT 100 MHZ IS 0.66 uM (MICRON)
>
>The variations due to different material is within an order of
>magnitude. If my memory failed me please quote the correct figure.
>I think the number is so incredible that everyone should know.

But current continues for some depth beyond that point. And don't try to
treat the conductor interior as insulation, it doesn't always work.

>On some previous posts RF current within the coaxial transmission line
>and outside the shield were discussed. The discussion centered on the
>effect of line length, particularly at 1/4 wave length and 1/2 wave

>is around 95%. Wouldn't this effect make any difference?

While we know what the inside TEM mode VF is, we usually don't know what the outside (common mode) VF is! It depends on the cable's surrounding environment.

From: w8jitom@aol.com
Message-ID: <4l2f9n$ql1@newsbf02.news.aol.com>
Source record: 202646

Hi Ray,
Let me be more specific. In article
<9603168296.AA829695757@mails.imed.com>, mack@mails.imed.COM writes:

> Maybe I need new glasses but I saw about 15 3-???, 3CX????,
>88??, and others made by Eimac mentioned as well as the 811 and 812
>made by RCA and others. SNIP
>There was not ONE SINGLE mention of a specific tetrode ANYWHERE in the
>article.

The lead, AND LARGEST, picture was a Svetlana 811A. What's wrong with a competitor's tube being pictured, or better yet an *original* RCA 811A ?

Look again at the references. They steer the reader directly to the author's own business. Only reference 2 does not. The articles referenced were all written (with the help of the author) to endorse or support the author's products. The "technical articles" referenced don't describe general tetrode operation, they specifically describe the advantages and use of the ****author's tubes****.

>The only direct reference to Svetlana as a tube manufacturer was the
>first footnote that said you could get data sheets for most of the
>tubes mentioned from Svetlana, *even if you happen to be using Eimac
>tubes* (emphasis mine). If anything the article was an Eimac ad!

Eimac ad? Where is Eimac's phone number, a picture of Eimac's product? Where is Eimac's address or a reference to any construction articles using Eimac's tubes? Funny, in your "Eimac ad" *every single one of those topics* are covered for the author's company, and ONLY that company.

Let's talk about getting "facts straight". I JUST CALLED Svetlana and talked to Pat. She said they don't HAVE Eimac data sheets, since Eimac is a competitor. But she would gladly help me find the closest Svetlana tube to the Eimac tube I was interested in. Some Eimac ad!

Read the "Next Revolution" section carefully. It:
1.) Downplays the cost and complexity of tetrodes, falsely claiming they are more simple to build and operate and some sort of "revolution".

2.) It falsely claims "The zero-bias revolution was ***NOT*** driven by technical performance".

Well, it most certainly was! Zero bias grounded grid amplifiers are easier to operate, more stable, have better IMD performance without regulated supplies, use less components, and are more compatable with the power levels of modern exciters. That sure sounds like good technical performance to me!

3.) The article paints the "tetrode from Russia" as "simple, inexpensive, modern, and high performance". Those are the exact words used.

>All in all I thought it was a very well written *historical* piece.

So did I, except the last section. I see little reason to extoll the virtues of tetrodes manufactured by the author's company in a historical article about the 811A, or tubes in general. I see no reason for only listing references leading back to the author's wallet.

>At the very least if we have a gripe let's get the facts straight!
>Especially if we air the gripes in public.

I hope I have MY facts straight enough now.

Have both the Alinco and the Icom. Alinco wins hands-down
on HF. No question. The ICOM folds under strong signals (like
when I put it on a 2 element quad).

However, CW filter in the ICOM is better but is optional not
included.

I have an R-70 that generates a "hash" on the SW bands; it is dependent in frequency depending on whether the dimmer switch is set. Anyone have a solution to this problem?

The HV power supply for the fluorescent display also generates 10V which is used by the IF as well, I believe.

I noticed at one of the MOD sites that the ICOM R-7000 also experienced a noise problem that was traced back to bad capacitors on the Display and HV PS boards.

Were there any ICOM service bulletins related to the R-70 concerning Display problems?

Personally, I think we need a consitutional amendment which
prohibits any person from purchasing any tube from anyone if
its use is in supposed "high end" (read that "absurdly priced")
audio equipment. :-)

Audiophiles out to tighten down their screws ... must be a lot
of loose ones in there. Oh well, fools and their money ....

Personally, I won't be pleased at having to pay several
hundred bucks for a replacement set of 807 modulator tubes
for my Viking II ....

Hello-

I am wondering why I need to ground my radio and power supply using a separate ground wire instead of using the the ground normally provided by a 3-plug AC connector? Wouldn't a separate ground create a ground referencing problem? I'm looking to understand what I need to do when I purchase my Power Supply this week and install my system over the weekend.

I will be using an IC 730 with the IC-PS15 Power Supply. Any help you can provide will be greatly appreciated.

If you havn't seen a HDTV demonstration go check one out the picture
is amazing. I watched a demo at the local art muesum, one Japaneese
short showed someone cooking in the kitchen. You could see very fine
detail on the hamburger and other items without really trying, you
could see the small droplets of greese flying off the frying pan. I'd
say it was easily as good if not better than any fine grained 35 mil
photo i've seen.

There is a HDTV newletter available on the WWW. Try www.web-star.com
some stuff is there as well as a full subscription. I don't have any
interest in the company, but the data is there.

For many years Eimac employees often authored amplifier article's for QST and I don't seem to remember anyone complaining about that. As long as the connection between the author and a company is specified, I'd say most of us have enough brains to judge for ourselves whether there is a conflict of interest.

Does the author of another construction project who markets a kit for that project have a conflict of interest?

Maybe--but I think if I am interested enough to buy the kit, then I probably am just happy to have the information to accomplish something I couldn't do on my own.

Besides, I am not sure there are any real sources for 811's today besides Svetlana. We don't use them where I work, but we do use some Chinese 5894 tubes. I can tell you that they are an instant way to turn what was a 100 watt 150 mhz. radio into a 70 watter. If I had some technical info, like in the article, I might be able to do something about that.

While it isn't simple programming, the 30-68 range (normally disabled on the international model) can be enabled by adding a diode in position D2. Reception may be slightly poorer in that range, as the front end is tuned for 68-88 MHz.
Download a Pro-43 modification file and follow the instructions to access the diode group. Ignore the instructions about D4 & D3, which are talking about the U.S. model. If you don't have a surface mount diode to install, a conventional signal diode should work with some judicious lead bending and soldering.

From: sakai@cs.sunysb.edu
Message-ID: <SAKAI.96Apr18164712@csws1.cs.sunysb.edu>
Source record: 202466

In article <dgfDpx8vK.4Hz@netcom.com> dgf@netcom.com (David Feldman) writes:

On the FT736 how do you copy a Memory to VFO? There is a V->M key and
a V<->M key, but no M->V key as far as I can see. Is there a trick to
this I never discovered?

I am using FT736M in Japan. I don't remember it precisely, but it can
be done by V->M key or V<->M key followed by Function key. (I am
staying Long Island NY and will be back this summer.)

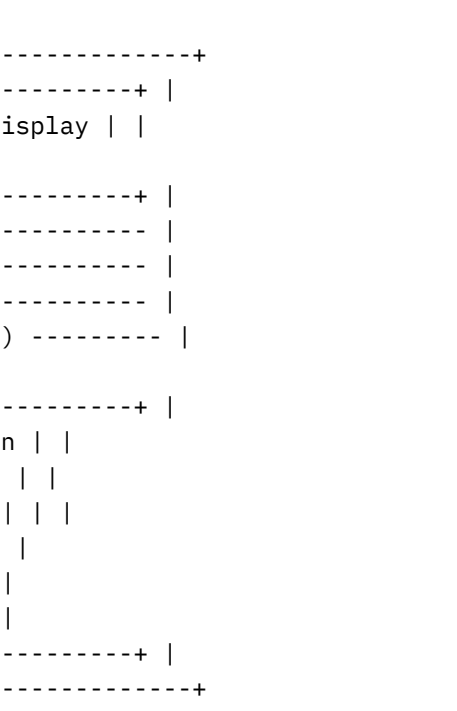
1047. FT-10R MARS Mods *here it is*

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-18 00:00:00 UTC
From: Josh Pavlovich <jpav@mtnweb.com>
Message-ID: <31772241.41E2@mtnweb.com>
Source record: 202467

Yaesu FT-10 Extended Transmit Mod for 140-174MHz use.

Be sure to set your mail reader to a mono-spaced font (like Courier)
to view this correctly.

1. Remove antenna and battery.
2. Locate the Ni-Cd battery sticker on the back of the radio chassis.
Pry up the corner of the sticker and peel it off carefully.
3. Remove the two screws located under the sticker. These retain the
keypad.
4. Slowly lift off the keypad. Use care not to dislodge the gasket.
5. Locate and unsolder the 0 ohm chip resistor at location "M" (see
diagram below).
6. Re-install keypad with two screws. Be sure gasket is properly
seated.
7. Replace the Ni-Cd sticker if desired. Reattach battery and
antenna.
8. Press down and hold the Top-Notch and Lamp button while turning
the
radio on.



= Location "M", chip resistor to remove

If memory serves me, the board actually has an "M" near the correct
resistor.

Bob (w5tkb@airmail.net) wrote:

: A tempest in a teapot!
: Bob W5TKB

Well said!

My QST has just arrived, and I quite enjoyed reading that piece. I too would consider tetrodes to require more involved circuitry than gg triodes, but, then, I'll probably find something I'm not in 100% agreement with in just about any article ;-)

It told more of a story about Eimac and RCA than about anyone else, the Russian bottles came over as simply copies of the originals. If someone from Svetlana can write in public in such a way, where their competitors are favourably treated, then I am pleased.

Let's recall all the articles that were written by engineers from RCA a long time ago, and thereafter by people from Eimac showing how to build amplifiers around THEIR products, Oh, yes, and Motorola RF power transistors...

I'm glad they wrote them, I'm glad the were published, I'm glad I read them. I learned a lot from them. They were not disguised advertising, they were quite open about their affiliation. I was free to try the techniques covered with other brands if I wanted.

I work for a commercial electronics company, HP, and I write things occasionally. Perhaps I could write a pure advertisement saying our products are "Awesome" and all others "Suck" ? would anyone in the market for (famously) expensive test equipment be swayed favourably by this?

I try to write good quality articles, with useful technical content, that are not tied to any specific brand of anything. In the Oscillators and synthesisers chapter of the ARRL handbook I had to mention equipment used for phase noise measurement. I made sure to be fair and to cover what the ARRL use and what I've had first hand experience with - which meant mostly HP, but I took care that this was done for those reasons and not for advertising. I made sure to discuss using other equipment to allow people to exploit whatever they can get their hands on, whoever made it, and I went as far as how to do good quality measurements with homebrew stuff and any old surplus wavemeter or receiver.

I was cautious in writing this section, I wanted to tell it "as it is" and get people going with thatever they have, and not be open to criticism of partiality in favour of my employer. We have competitors,

and many of them are very capable indeed, we have to work hard to keep up or keep ahead (depending on your opinion of the relative merits of the various test equipment makers).

My bosses were happy for me to write, and trusted me to get on with it... as an R&D employee, they have first rights to any inventions or writing that overlap company activities, so I have to get their permission. They did not even wish to see it before publication.

If I did a good job on that chapter, and my associations are no secret, perhaps it reflects well on the competence of the people in our firm? though it was a purely private undertaking in my own time without any company backing other than "Yes you can if you want"

People with professional/commercial connections have access to a lot of information that I would not want amateur radio to be cut off from. I've greatly enjoyed the articles written by Ulrich Rohde, and found them technically stimulating - now, isn't HE is the son of one of the founders of the major competitor of the division I work for ? That is one of the joys of being involved in amateur radio, I get to see things outside of my immediate employment, and I can play with things that are not constrained to the current project.

I came away from that triode article with the impression that it was interesting, well written, and impartial.

Count me in on the side of those who object to QST articles where software necessary to some project can only be got ready programmed into a kit from the author. These are not constructional articles, but rather kit assembly instructions being published, and if the kits include the instructions anyway, and there is no way to build one without the kit. then what purpose does the article serve other than advertisement ? In the case of a 1 chip processor and a few components, 100% of the thing lies in the software - without people seeing the software how can there be any learning and self-training ?

Cheers
David GM4ZNX

Hello, My name is Cal.

I am getting interested deeply in 6m allmode and EME.
I have a YAESU FT-990dc w/35 amp external supply in perfect
condition that I bought last March 95. In order for me to
get the allmode equipment I will have to sacrifice the
990 and supply... cost 1800.00 plus after shipping and will
sell for 1400.00 firm. This setup allows the Nice HF you
want and you will have a 35 amp supply to run it and your
whole shack.

Also for sale is my LK500zc Amp Supply 2kw amp... Legal Limit
plus.... it is in beautiful condition and well cared for.
I installed 2 brand new 3-500zg tubes (graphites) for the
heck because it had the same tubes in it from the beginning.
I did not see an appreciable power gain so the old tubes were
in great shape (sold the old ones). I figure the graphites
will never have to be replaced... will sell for 1300.00 firm.

All prices are firm and you pay for shipping....

DAVID..............

I WILL PUT THIS IN CAPITAL LETTERS AND REAL SIMPLE WORDS SO, MAYBE,
YOU CAN UNDERSTAND IT. YOU ONLY HAVE TO POST A MESSAGE 1 (ONE) TIME.
PEOPLE HERE ARE QUITE INTELLEGENT (SMART..). FOR THE 4 (FOUR) ITEMS
YOU HAVE FOR SALE, I THINK YOU HAVE POSTED ABOUT 40 (FORTY) POSTS!!!!
THIS IN A PERIOD OF 5 (FIVE) DAYS! THIS SERVES ABSOLUTELY NO
PURPOSE, AT ALL, EXCEPT TO PISS READERS OFF!! EVEN AFTER ALL THESE
POSTS, I DOUBT ANYBODY STILL KNOWS WHAT YOU HAVE FOR SALE OR WHAT THE
EXACT PRICE IS, EITHER. TO SAY, YOUR DESCRIPTIONS LEAVE A LOT TO BE
DESIRED, WOULD BE AN UNDERSTATEMENT!

POST EXACTLY WHAT YOU HAVE (YOU "CAN" PUT MORE THAN 1 (ONE) ITEM IN A
POST TOO!) 1 (ONE), I SAID 1 (ONE) TIME! PUT ALL DETAILS ABOUT THE
ITEMS IN THE POST. BRAND, MODEL, ACCESSORIES OR OPTIONS, PRICE, ETC.
AND HIT THE SEND BUTTON 1 (ONE), I SAID 1 (ONE) TIME!! IF SOMEONE IS
INTERESTED THEY WILL PROBABLE EMAIL YOU OR CALL YOU OR POST A REPLY.

NOW THAT I'VE SAID THAT, THERE MIGHT EVEN BE A BETTER PLACE TO POST
YOUR FOR SALE ITEMS. I'M NOT SURE IF FOR SALE IS A CORRECT POST FOR
THIS GROUP OR NOT. I'M SURE SOME OF THE READERS OUT THERE WILL HAVE
THE ANSWER FOR THAT.

Nothing above but by adding a small surface mount diode to a vacant position
(D2 - you need both D2 & D3 in place to have 30-88) on the lower logic board
you can have 30-88MHz. (Assuming you have a PRO-43 from oustide USA/Canada).

What you guys need is a cellular phone designed for the ETACS system,
which is the dominant system in England and much of south east asia.
They can be found at ham fests with some carefull searching. The tx band
is 872-915 Mhz stock.

Sorry to say that many times hams get way to obsessed with receiver noise figure, especially on hf. Atmospheric noise is
easily many (10+) dB above KTB (thermal noise) thus rendering the best noise figure of no value. A 2 dB noise figure on an hf
radio front end is just fine. In fact, you don't have to look too far to find a very low noise device being used in a circuit
that is too wide band, or not high enough Q to actually achieve its ultimate noise figure. That 2dB NF device may be
performing just as well ON THE BENCH as someone elses 1dB device.

>for my Viking II ....
>
>Grant/NQ5T

I have 807's for $10 each, if your interested. And I don't sell just audio tubes. I supply sweep tubes at prices well below places that specialize in dealing to hams, and in fact supply some of those dealers. So while some dealers charge $45 or more for a 6LQ6 I charge $35 for one or $30 each in quantity. I just sold new old stock 8950's for $45 each (sorry, I have no more) and RF parts sells them for $75 each.

While there are certain brands of small signal tubes that I pay a higher price for, there is still in most cases a cheaper version for people that don't want to pay the price. Example is Dutch made 6922's which I like. You can buy tons of Sylvania 6922's for low bucks. Very very few audio tubes that are expensive have affected the ham tube pricing at all, or your ability to get replaceable parts. 8417's are very rare. Hard to get. But the price for them has been driven by hams as much as audio guys.

So while some high-end equipment is absurdely priced (I agree) the effect on the ham tube biz is negligable.

The fact is that my post states I will pay more than the usual tube dealer (Antique Electronic Supply, etc) for stuff I like or I'm out of. I think most people appreciate that.

Regards,

Kevin Deal

Take your MARS permit to an authorized Yaesu dealer and they will provide
you with the mod info. If you are not authorized to operate out of band,
don't expect much cooperation.

>
>I will be using an IC 730 with the IC-PS15 Power Supply. Any help you
>can provide will be greatly appreciated.

The power supply will have a third wire safety ground, but the radio
still will not. So you'll want to also give it a chassis ground
connection. It has a lug for that purpose. You could tie that to the
third wire connection of the outlet you use for the power supply.
That would give you ordinary electrical shock hazard protection.
(The DC negative lead won't serve because it isn't directly
connected to chassis either in the power supply or the radio.)

The problem is that the house electrical third wire ground won't
do much for you as lightning protection. The ground path is too
long, and has far too much inductance. You're also right to be
concerned about ground loops. They can be damaging.

The answer to both problems is to create an entrance panel that
serves as a shack ground window. This is a copper plate to which
every wire that enters or leaves your station is connected *before*
going on to connect to equipment in the station. The wires should
be either directly connected to the plate in the case of "grounds",
or via appropriate suppressors if the wire is nominally "hot". This
means coax, power wiring, telco wiring, etc. This plate becomes
your station "single point" and shorts any potential ground loops
entering your station.

This ground window is then connected as directly as possible,
using as low an inductance wiring method as possible (5 inch
wide smooth solid copper strap preferred, don't use braid), to a
good Earth ground connection. A single ground rod is generally
not a good Earth ground connection. I recomend a minimum of
4 rods, with a central rod surrounded by the other 3 arranged
around and connected to the central rod in star fashion. The rods
should be separated by at least twice the length of a single rod
from each other to avoid the charge saturation zones overlapping.

This is often a sufficient Earth connection where the water table
is high. In other areas where soil conductivity is poor, I'd add a
Ufer ground (rebar in concrete) at least 20 feet on a side, and/or
a bunch of buried radials to form a capacitive "plate" to couple
energy to Earth. Dirt is a pretty poor conductor, with most currents
conducted soil grain to soil grain by arcing across the grain boundaries.
So surge currents are most effectively conducted to Earth via capacitance,
with the Earth forming one plate of the capacitor.

This system will give you an effective lightning safety ground,
and incidentally it may also serve as a RF ground should you
need one, providing the connection between the ground window
and Earth is (very) short compared to a quarterwave at the highest
frequency you'll be operating. Note, you usually will *not* need
a RF ground unless you're trying to feed a long wire or other
grossly unbalanced type of antenna. Verticals should be worked
against a ground *at their base* and not a ground back at the
station. Dipoles and other balanced antennas don't require a
RF ground connection.

You'll have to be the judge of how much grounding you want to
do. I wouldn't sleep easy in thunderstorm country with a lesser
system than the one I've described. If you aren't willing to
put in an effective system, you might be better just letting
the station "float" with respect to Earth and religiously
disconnect (and separate) antenna downleads from your equipment
when you aren't operating. Note that word "separate", lightning
that has just traveled miles through open air isn't going to
be deterred by a few inches of separation. Give it a better
choice of path than jumping to your equipment, or you.

Hi Bob,
In article <3175C21C.258A@airmail.net>, Bob <w5tkb@airmail.net> writes:

>Seems to me to be much ado about nothing! Before I retired, it was
>common in my company to have sales folks come in and complain about
>article in trade journal extolling the virtues of a new system just
>installed from Timbuctu to Swaziland by XYZ Corp. The article covered
>all of the technical issues involved and how XYZ solved them with their
>new Slopbucket radio system. What's different?

Plenty. QST is considered a technical publication for the membership, not
a "trade journal". "73" and "CQ" are trade journals, if you call our hobby
a "trade". Membership publications or journals are more like the
"Proceedings of the IEEE" and "QST".

Readers depend on QST for unbiased technical information, not skewed
articles that misrepresent fact. I have no object to a large paid ad by
Svetlana, but not a free of charge combo article and ad. **Especially
not** when the article misrepresents or distorts technical fact.

>I would chide those who complain and suggest they
>submit an article. It's great advertising. I'm sure QST would welcome
>similar inputs from Eimac or whoever.

Actually QST does not welcome such input, they flatly refuse it!

They (as they still claim) refuse to accept articles that may contain a
conflict of interest. The refusal to mix business and technical data is a
key way to help insure technical data is unbiased.

>Every construction article (or
>most at least) have and ad in the notes telling you where to get parts
>(or EPROMS programmed by Ole Joe's Widget Shop) etc. Again, what's the
>difference - none in my mind.

None in mine either, if other available (alternate) sources are also
listed. And also if *** unbiased technical data*** is presented in the
article. So we agree on that.

>I think it's neat that someone is still
>making tubes for all of those 811A sockets -- RCA sure as hell ain't.
>If Svetlana can make a quality product for less, then power (pardon the
>pun) to them.

Me too. They aren't the only source, but at least the article was about
the history of that tube. I find no fault to the 811 section of article,
except the omission of Chinese and surplus sources where thee 811 is

available.

My objection is to the "plug" for tetrodes manufactured by the author's company. What does that have to do with the history of an 811? I alsso object to misrepresentations extolling virtues of tetrodes and the listing of reference articles telling the readers how to find more articles extolling the virtues of the author's tubes.

Is QST changing it's policy, and allowing free ads? Are they now allowing "for profit" technical articles? If so, wouldn't it be a good idea to sharpen up technical editing and make the new policy known to readers that depend on unbiased technical information?

If this was 73 Magazine I'd expect it, if it was CQ I might think about it a little bit. But QST has always had high technical standards, it's a shame to see the standards errode. QST was always above allowing self promoting articles, it's a shame to see that occuring more and more frequently.

How can a reader know what he is reading is unbiased fact, or a "for profit" distortion, when manufacturers are allowed to publish technical articles extolling the virtues of their own products through QST?

>A tempest in a tea pot
Or a warning sign of deteriorating standards?

73 Tom

1076. Heathkit HR-1680

Source record: 202548

I'm looking for information on the old Heathkit HR-1680 ham-bands-only
receiver. It was manufactured in the late 1970s.

What is its basic design (direct conversion, superhet)?
What IFs (if any) does it use?
Is it all solid-state?
Does it perform well (dynamic range, sensitivity, AGC)?
Does it have a built-in power supply?
What is its overall quality?
What is a typical price for the unit on the used market?

Any other info...?

Thanks for any information you can provide.

Hi there, name here is will. I have a kenwood tk930 LTR-trunked/conventional mobile. the radio has 6 systems. trunked systems can have up to 6 subgroups, conventional systems can have 4 channels per system. You can program trunked and conventional systems simultaneously .The radio supports pl and dpl conventional signalling and is telephone interconnect capable. RF power is 15 watts. I will program and ship for $325.
The second radio is a motorola stx single system portable. Can be either motorola trunking or single channel conventional. Also supports pl and dpl in conventional mode. Asking $200 programmed and shipped. Both radios have been checked out on the bench and are in perfect working order. Contact me at 617-491-2680 till 11 pm est or email. 73,
Will, N1PXA

1086. Ham Gear For Sale Getting Out

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-18 00:00:00 UTC
From: braymer@InfoAve.NET
Message-ID: <01I3OZ80HJ3690TAA5@InfoAve.Net>

Here is a list of ham gear and other stuff i have for sale
i am getting out of the hobbie and going too do some thing
else.

Yaesu FT-301SD HF 160-10 meter Radio with FP-301 Power Supply
And Manual NO Mikephone.The Radio is in Near mint-condition and
works real well,this is the low power radio of the Yaesu 301 line.
Cover AM,CW,SSB. $550.00 shipped

Alinco DR-130T Two meter mobile radio with manual,Touch Tone
mikephone,mobile mounting bracket.Encode/Decode board
need finals put in. $175.00 shipped

MFJ-981 3killowatt antenna tuner works fine near mint-condition
$190.00 shipped

MFJ 1270C Packet TNC use only onces with manuals cable $115.00 shipped

Alinco DJ-F1T HP Two meter HT ONE MONTH OLD with extra Highpower
battaray pack and charger,With manual and Box $295.00 shipped

All gear include shipping US Postal Money Orders Only
If intrested Email too Bobby Raymer AD4HL at braymer@InfoAve.Net

Press the user key while turning on the transceiver, then press the
key you want to duplicate. The factory setting has the user key
duplicating the BAND key.

Wes Shull wrote:
> Alinco DJ-G5TH

I have a G5, and it's pretty cool! I use the channel scope now and then, too.

I'd consider the new Yaesu FT-50R, too. It's $340. It might be in a rather different category, though, since it has fewer features (e.g. receives only one frequency at a time) and is smaller. If you get one, let me know! I bet it's great for hiking.

We might even be able to talk on linked repeaters, e.g. via the Malad remote, by the way.

Yes, the Standard C558A is quite comparable, feature-wise. It's great. Talk about a well-designed user interface. I have a friend who has one. There's the C568A, too! But, they're more expensive. See:

1) STANDARD C558A, 2M/440 MINI HT ENC/DEC 40 MEM $529.95, In Stock (minus $30, rebate)
1) STANDARD C568A, 2M/440/1.2 HT W/ WIDE RX $599.95, In Stock
5) YAESU FT-50R-HP, 5W 2M/440 HT W/ EXPANDED RX $339.95, In Stock
1) YAESU FT-530, 2M/440 HT 2W ENC/DEC DTMF PAGING $369.95 (minus $70, coupon)
3) YAESU FT-51R-HP, 2M/440 5W DUAL BAND HT $519.95, In Stock (minus $30, coupon)
2) ALINCO DJ-G5TH, 2M/440 HT W/ 5W BATTERY $419.95, In Stock (minus $10, rebate)
1) ALINCO DJ-582T, 2M/440 DUAL BAND HT NO 800 RX $354.95, In Stock
4) KENWOOD TH-79A(D)-HP, 2M/440 HT W/ 5W BATTERY $479.95, In Stock (minus $20, rebate)

That's from http://www.hamradio.com/search/adv.html .

Call Roger at Standard, at (312)763-0081 to get info about those Standard radios. Sure wish he would update their web pages someday.

Well, that's all for now.

Gary

A lot of people like their 736's - it depends what you use them for,
but it is a fact that they do not have as good a receiver as the Kenwood
or Icoms and the ARRL labs testing points this out. They are especially
bad on 70cm. See the note under this topic about that. For hams not
trying to pull out weak ssb signals 10 khz away from a 59+40 local signal
they may work fine, but they are not well suited for weak signal work. I
am glad you like yours though.

A trivial issue indeed. In past decades ham magazines featured build it
yourself rigs using tubes made by only one manufacturer!
We built them...where do you think all those 4x250, 300,
800 articles came from. The best paper on transmitter construction
was "The Care and feeding of Power tetrodes" by Bill ORR
W6SAI. who I believe was long associated witht the Eitel-McCullough gang.
:-)
My Point: Articles using proprietary tubes got us building and so what.
The Svetlana article was informataive far beyond its
comments about the 4CX1600. Lighten up and learn.

:>
:>Does anyone know if a newsgroup exist where HDTV issues are discussed?

Best place for HDTV information, what little there is at the present time,
is: sci.engr.television.advanced and/or sci.engr.television.broadcast.

:> The projected cost figures of the HDTVs are extremely high compared to
:>current TVs. I suspect the majority of american families will be unable to
:>come up money for the HDTVs.

True, the conversion will be a major economic drain on both the broadcast
industry and the consumer. Broadcasters face conversion costs of up to $35 million per station over the next ten years or so. Even with the expected reduction in per-set costs, the consumer can probably expect to pay more than $1,000 for an HDTV set (28" diagonal, about the same picture
height as a current 21" set).

:> Since HDTV transmissions will be incompatible with the current NTSC
:>transmissions, is it possible and likely that TV accessory manufacturers will
:>come up with an economical convertor box to convert HDTV transmissions into
:>NTSC signals, so that HDTV broadcasts can be viewd by regular NTSC TVs?

There are already several companies planning to build set-top converters.
However, the converters will not be able to provide many of the features of HDTV (wide screen, 1700x1000 resolution, etc) of a dedicated HDTV receiver.

:> Your comments on the topic are appreciated. Please email your response
:>to pmzone@clearlight.com. Thank-you

I have had the opportunity to view several HDTV demonstrations, most recently
at the National Association of Broadcasters Convention this past week.

At
the NAB convention, I compared the effect of HDTV programs on a
conventional
receiver (aproximately the same picture height as a 25" set) and a large
screen (projection) system. HDTV really shines on the projection system
..
the effect is not nearly as dramatic on the conventional receiver
(compared
to the normal "in studio" picture).

One *BIG* advantage of HDTV is its fully digital nature ... the digital
transmission takes advantage of error correction and concealment. If
you
receive a picture, it will be perfect ... no ghosts, no noise, no crap.
However, any problem (including TVI, folks) will likely cause complete
signal/picture loss.

>:-)

I would never object to a technical article that accurately described how to build a tetrode amplifier, or correctly listed the advantages of a particular design.

I do think incorrect technical data presented to make the author's product appear more favorable, while making the competition's product look out of date or less fit for the same application, is out of place in any article.

In spite of all the personal opinions and off -the- cuff comments, I haven't heard a single comment directly addressing my original concern. My puzzlement is:

1.) Is it OK to use a "free" article to pitch your products while slighting the competition? Is that good ethics? I'm not sure, please tell me.

2.) Will it cause any long term problems if magazines with good technical reputations allow manufacturers to do this as a practice? Will it hurt the reliability of the data people trying to learn receive?

I wonder if anyone can help with the actual questions I have, rather than what they think was asked?

Also, watch out for some companies advertising "9913 Equivalent" coax in some of the ham magazines. I bought a 500 foot rool from Cable Experts that was pure junk, and even short runs of it were totally useless on 1200 Mhz. I agree that it is a suitable coax, and you should not have any problems finding type N connectors to fit it. The new 2 piece type N connectors work real nice on it. I also agree that there are other coax alternatives though. THe LMR series is good, and also I've had very good luck with the new Cushcraft Ultralink coax. It is much cheaper than 9913, and the spec's show it to be slightly less lossy at 1000 Mhz.

Also, I don't believe that 9913 has a non-c0ntaminating type jacket.

>Steve Ellington N4LQ
>N4LQ@GNN.COM

'Yo, Steve,

Some companies are SO cheap, they use a resistor and heat shrink to keep the crystal at a semi-constant temp.

International Crystals 'usta have them. Most ovens use quite a bit of current.

How much space do you have to spare? I have some that use 6 or 12 VDC and plug into a octal scocket. I have others that are 6V and 12V.

Better yet, go to a two-way radio shop and ask for one. I'll bet you can get one for free!

Look too at the entry level of VCR prices back about 10 years ago
and compare them to today. Ditto that for computers and just
about any electronic equipment you can find.

One of the original four function, no memory calculators I
priced was $300 in 1970. Today we have solar powered,
credit card sized calculators with multiple functions
plus memory for under $10 retail. Who'd a thought
that.

Bottom line is that the production line determines the
volume and drives the development of equipment
with more functionality at lower costs over time.

Heck, even ham equipment sees that. Look at the
price of a full function, multi-mode transceiver
these days. Yes they cost over or around $1000,
but that's cheaper than anything close to the same
capability that was offered 15 years ago. Factor in
the inflation factor and you have ham equipment at
lower prices with greater capabilities than ever before.

Hello, My name is Cal.

I am getting interested deeply in 6m allmode and EME.
I have a YAESU FT-990dc w/35 amp external supply in perfect
condition that I bought last March 95. In order for me to
get the allmode equipment I will have to sacrifice the
990 and supply... cost 1800.00 plus after shipping and will
sell for 1400.00 firm. This setup allows the Nice HF you
want and you will have a 35 amp supply to run it and your
whole shack.

Also for sale is my LK500zc Amp Supply 2kw amp... Legal Limit
plus.... it is in beautiful condition and well cared for.
I installed 2 brand new 3-500zg tubes (graphites) for the
heck because it had the same tubes in it from the beginning.
I did not see an appreciable power gain so the old tubes were
in great shape (sold the old ones). I figure the graphites
will never have to be replaced... will sell for 1300.00 firm.

All prices are firm and you pay for shipping.....
Either by check, money order, or C.O.D. only
.... 73 ....Cal, S9PLUS@gnn.com

1110. Re: QST conflict of interest Again!

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-19 00:00:00 UTC
From: w8jitom@aol.com
Message-ID: <4l7a4o$o18@newsbf02.news.aol.com>
Source record: 202482

In article <4l6h44$f7j@newsbf02.news.aol.com>, billn9hh@aol.com (BillN9HH) writes:

>
>For many years Eimac employees often authored amplifier article's for QST
>and I don't seem to remember anyone complaining about that. As long as
>the connection between the author and a company is specified, I'd say
most
>of us have enough brains to judge for ourselves whether there is a
>conflict of interest.

A construction article where the user has his choice of tubes is one thing, especially if the author is careful to describe correct circuit operation.

For example, consider a 3-500Z amplifier. The builder could always use Amperex or other brands of his choice. Even a factual technical article about a tetrode, using a Svetlana 4CX1600 wouldn't be objectional it explained why and how to select the various components.

When an article has little technical information, and includes picturesque descriptions of a particular product not even within the scope of the article... but manufactured by the author.... it's gone a bit too far.

That's never occured in articles written by Eimac or Collins Radio employees, they are basic cook book type articles with sound technical foundations.

I've never seen Eimac employees describe their tubes as "modern, high performance, inexpensive" while directly describing the competition's tube design as "not driven by technical performance" and "driven by simplicity, low cost, and superb product promotion".

Have you?

Help!

I am a SWL for six years and now decided to get a full licence. But the problem is that the prices on equipment are very high. I understand that they are very high worlwide, but our incomes level are still rather low and at the same time I am a student - to me buy something is even more complicated.

Maybe, anyone have old, but still useful, or a bit broken transceiver and can sell it for a realy low price (or even make a gift)?

Thanks in advance,

Gintas, LYB-77

I don't have my old Heath catalogs anymore, but I thought this was a
big tube-type receiver made in the mid 60's. Perhaps the companion to
the Apache transmitter or the Mohawk?

>their gills.

I don't have a mega-buck tube amp, but it's not for lack of trying. I
first heard the difference years ago, but too late to pick up a
McIntosh or even a Hafler-designed Dynaco at a reasonable price.

Incidentally, I wasn't kidding about the tests. At one time, I did
double-blind A-B tests over and over because I didn't believe it
either. We tried all kinds of tube amps, from the lowly Scotts and
Fishers up through the most expensive McIntosh. The solid-state
units included some of the best in their day, such as Mark Levinson
(Class A), Ampzilla, Yamaha and the better Harman Kardons. After a
few minutes of listening, I was *consistently* able to tell the tubes
from the transistors.

Incidentally, one guy I used to know had hearing that was apparently
even better than mine. He worked at a high-end retail outlet and had
somehow learned to recognize the sound of various solid-state audio
power amps. We could switch in an Ampzilla or a Bose or a Yamaha, and
he could name the brand. After I saw him do that, I never again
questioned the fact that this equipment all sounds different. I also
never again accused anyone of not hearing something just because I
couldn't. ;)

Be careful buying a used mobile rig. If it was actually used mobile,
it probably took more of a beating than its "full-size" cousins.

There are many good used desktop rigs around. Why not give Ten-Tec a
call and see what they have in stock? Depending on your budget, a
Corsair, Corsair II or Paragon might be a good choice. They also have
a free trial period and probably the best customer service on the
planet.

Yes, I have seen many instances of Eimac, and if you go back far enough, RCA, and others touting their products while dismissing other brands as lesser quality.

I believe the author, in this case, was referring to the lesser quality imported tubes we've seen over the last few years, not Eimac, etc., as per the 5894s that we use. There have been some 811s available that could not even be used in some amps as replacements because they were so far from the original spec that they could not be used in a horizontal position, etc.

I still don't see much difference between the parts kit--the author has selected what is in the kit thus giving us no choice. I have done very little ordering of such things, but when a complete board kit is offered, it doesn't seem to me there is much choice on the part of the purchaser. Whether the seller is selling at cost to promote the project, or is making a healthy profit, I can't say. Most would consider the convenience of getting everything from one source at least some offset of any profit by the vendor, I suppose.

Finally, if you have a gripe, if you are a member of ARRL, you should be talking to your director about your feelings. I say again, I think most of us have enough brains to decide whether something is a conflict of interest. The League's job, mainly, as I see it, is to provide information and assistance to the ham community, and I believe the article in question does that. And, apparently, so do about 75% of the replies I've to you original.

This might help you ..

IC-2340H IC-2350H
Cross Band Repeater Access Codes

FRONT PANEL ACCESS

1. Set the radio for desired frequencies.

2. Push [VHF MAIN], [UHF MAIN], and [SET] simutaneously.

4. To turn off the repeater press [SET] for 1 second.

SETUP FOR REMOTE ACCESS

1. Set the IC-2340H to desired frequencies.

2. Press [DTMF/SCAN] until "REMO" is shown on display.

REMOTE ACCESS (sub band frequency is the control frequency)

1. Enable the control frequency by holding the [MAIN/SUB]. This
will place "SUB" on the display.

2. (Remote Control on) Press [B], {password}**, and [#].
"REMO" and "SUB" will flash on IC-2340H display.

3. (Repeater on) Press [D], [B], and [*].

4. (Repeater off) Press [B], {password}**, and [#]

5. (Remote control off) Press [B], and [*].

** Password is optional if enabled through the setup function of the
radio.

IC-2700H
Cross Band Repeater Access Codes

FRONT PANEL ACCESS

1. Set the radio for desired frequencies.

2. Hang Time- Push and hold [VHF MAIN], [UHF MAIN], and
[SET/LOCK] simultaneously until "L" flashes
on display.
3. No Hang Time- Push and hold [VHF MAIN], [UHF MAIN],
[SET/LOCK], and [DUP/TONE] simultaneously until
"L" flashes on display.

4. To turn off the repeater press [SET/LOCK].

SETUP FOR REMOTE ACCESS

1. Set the IC-2700H to desired frequencies.

2. Press [DTMF/SCAN] until "REMO" is shown on display.

REMOTE ACCESS (sub band frequency is the control frequency)

1. Enable the control frequency by holding the [MAIN/SUB]. This
will place "SUB" on the display.

2. (Remote Control on) Press [B], {password}**, and [#].
"REMO" and "SUB" will flash on IC-2700H display.

3. (Repeater on) Press [D], [B], and [*].

4. (Repeater off) Press [B], {password}**, and [#]

5. (Remote control off) Press [B], and [*].

** Password is optional if enabled through the setup function of the
radio.

IC-820H
Cross Band Repeater Access Codes

1. Add diode on blank position between D27 & D28. Part number is
a 1SS353 P/N 1750000390.

2. Set lock mode by pushing [LOCK].

3. Turn Power off

4. Hold [M/S] and turn on

5. To turn off mini repeater push [LOCK]

IC-281H
Cross Band Repeater Access Codes

FRONT PANEL ACCESS

1. Set both bands to desired operating frequencies.

2. Hold [BAND/SPLIT] and press [[SET/LOCK]. A Flashing "L" will
appear on the display.

3. To turn off the repeater push and hold [SET/LOCK].

The IC-281H will receive on UHF and retransmit on VHF only

Message-ID: <4l82u5$hu9@pacific.mps.ohio-state.edu>
Source record: 202494

I've recently restored and aligned a nice round emblem KWM2. It seems to work perfectly, except for a glitch with the ALC. When the PTT or VOX relay is first closed, the ALC meter pins momentarily. After a second, the meter recovers and the ALC appears to work normally (until the next time the relay is closed). Before I spend an evening chasing down the problem, I'd be interested in any suggestions from you Collins gurus out there. Thanks.

1123. Re: QST conflict of interest Again!

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-19 00:00:00 UTC
From: blood@austin.ibm.com
Message-ID: <4l84b7$24s6@ausnews.austin.ibm.com>
Source record: 202495

Let me put my 2 cents in. I published an article in QST in July of 79,
"A digital Morse code clock". I cannot recall what motivated me to do so at
a young age of 26. What I remember about the experience was bitter sweet.
I poured my heart into the project, trying to write with a typewriter,
(no computer word processors then), drawing schematics, trying to be interesting.
Yes, this project had a EPROM that I was willing to program for the readers.
And yes, I stood to make about $2 per eprom that I sent out. So I guess that
this was for profit. Well, let me remind you that QST did NOT pay anything for
the work, I did not even get an extension for my subscription. This was
very disapointing. The entire motivation was just the fame and glory I guess.
Well, anyway, the article did go out. Someone else decided to make a PC board
for the project and market it. This was not my idea, and I was lucky to get them
to send me one board for evaluation... Well, the article went out and over
the next 2 years, some 100+ people actually sent me for the EPROM. It was a lot
of hassle, I had to package them up, and mail them out. I even has one
character send me a bad check! (for just a few dollars) I had one person
send me a note explaining how he thought it was the worse article he had
ever read. (I still remember that). To sum it it, I am working on
another similar article, and If I ever get it done, its going to anyone who
will pay first. I cannot hold it against these authors if they package a
kit and try to make a buck off of this work. It is a LOT of work to
create one of these articles. Look at the repeater control circuit a month
ago, they are trying to sell the project as a kit. I bet their profit
after selling about 100 of them will amount to about $1.98/hour for their
work. So quit the griping about these articles, or you may just not have
any more of them to read....

1128. Re: QST conflict of interest Again!

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-19 00:00:00 UTC
From: w8jitom@aol.com
Message-ID: <4l8771$1h0@newsbf02.news.aol.com>
Source record: 202500

Hi All,

Let's not talk emotionally about what the artical "feels like or reads like", but what it says. If someone can explain the following to me, maybe I'll change my opinion. But hyperbolic comments like a "tempest in a tea pot" and so on don't address my concerns, and neither do other general "well I think other people have done it" responses. So someone help me with facts, not feelings.

Let me once again clarify... I have no objection to the first part of the article, the part I think is self-serving bunk is the section "The Next Revolution-High Performance Tetrodes'. Without that section, the article would have been very well written, unprejudiced, and truthful.

For example...
In article <Dq2A1E.4Bo@hpqmoea.sqf.hp.com>, dstock@hpqmdla.sqf.hp.com (David Stockton) writes:

> My QST has just arrived, and I quite enjoyed reading that piece. I too
>would consider tetrodes to require more involved circuitry than gg
>triodes, but, then, I'll probably find something I'm not in 100%
agreement
>with in just about any article ;-)

And hence my main point. Can anyone address these questions?

1.) Tetrode PA's are more difficult to operate, construct and design that GG triode amps, the author's contrary statements were technically false. Please explain why tetrodes were incorrectly described as a new "technological reveloution" and listed with advantages they (in fact) do not have?

2.) Why were tetrodes even mentioned in a article about 811's? What do they have to do with 811 tubes?

3.) Why were the references (with the exception of one to an out of business company) only to other articles supporting the author's sales of tetrodes and to the author's company?

4.) What technical or historical function does any of this have, other than to promote the author's tubes over triodes?

> It told more of a story about Eimac and RCA than about anyone else,
>the Russian bottles came over as simply copies of the originals. If
>someone from Svetlana can write in public in such a way, where their
>competitors are favourably treated, then I am pleased.

But they didn't do that. They directly painted Eimac's zero bias tubes, in the closing section, as "not driven by technical performance" and "driven by simplicity, low cost, and Eimac's superb promotion". They inferred the Eimac tubes are old technoligy.

That is either self-serving criticism of another competitor or it is a simple technical fact. Since it is not a true technical fact, it must be self-serving propaganda. Someone please correct me if I've made a technical error in this. I want to be fair.

>the work, I did not even get an extension for my subscription.

Roger, I'm sorry that happened, but it has nothing to do with my position. Your motivation was clear, your goals honorable

I assume you didn't commercially manufacture the subject of your article, and I also assume you didn't at the end of that article tell the readers "the competition's products are out of date and were driven by simplicity and good marketing, their designs were not driven by technical performance. My products that are not related to the subject of this article are revolutionary, simple, inexpensive, and result in a product that is significantly less expensive."

Any article that contains a summary like that should have the self promoting hyperbole edited out. The article I refered to contains that exact type of self-serving and unnecessary garbage. It not only is self promoting, it is technically untrue.

In all the "it ain't no big deal" arguments, I've yet to see anything directly addressing and reputing facts. The replys run the gamut from "cute but well worn cliches" to replys about other subjects or other articles in general.

No one has responded to the specific area of my concern.

LIKE some of the other posters here, I personally appreciated the info presented in the article. I had just received a new set of 4 572B's from Svetlana, and appreciated as much supportive info on their products as possible - regardless of how that info was titled. As already stated in this thread, tubes currently availble from Svetlana appear to be of good quality, reasonably priced, and available in types no longer available from other sources where they were previously offered. To get all torqed up over such a trivial non issue suggests the original poster either simply was experiencing a bad hair day or just has too much time on their hands and not enough *REAl* things to do....

You have to realize, most internet providers don't offer ALL of the newsgroups so people have to post wherever they can. I much rather see FS items than the bickering about code or no-code.

My internet provider gives us only 3000 of over 15,000 available newsgroups.

Tom,

You inferred far too much from the article. I'll even go so far as to say that it's possible *your* biases colored *your* inferences.

I read the article and didn't see any "self-serving propaganda". Yes, it was written from the author's knowledge base and personal experience, but I always accept that fact when I read, watch, or listen to anything. If you had written the article, I'm sure it would have reflected your opinions.

I saw an article, which of necessity was terse (printed in a magazine), that provided valuable insight into several types of tubes and their origins. But then again I wasn't looking for anything else.

>Any ideas?
I have the same radio with the squelch board. I'm sure the accessory came with a schematic. There is at least one point which should toggle between HI and LO as it detects CTCSS. If you don't have a schematic, check the I/O or internal pins as you toggle a test tone squelch signal off and on. Once you find the voltage that jumps up and down, use it as a logic source for your controlled device.

Paul-

I was aware of these facts when I got my IC-706. I was somewhat surprised
to find that the pre-amp was needed, especially above 14 MHz.

I came to realize that the problem was not RF signal-to-noise ratio, but
lack of gain. I would just run out of volume control. This is especially
noticeable under mobile conditions, where there may be competing
background noise in the vehicle.

They work fine for weak signal work -- I've used mine on 432 EME with
good results. Normally, in the weak signal part of the band there are
no strong signals (at least in my location) so I'm not sure that the
theoretical weakness is really a problem under real-world conditions.

Steve,
You don't NEED to ground things with a separate ground. Sometimes
you can get away with the AC ground. Separate grounds for the radio
gear are helpful when you start experiencing RFI problems. I have run
plenty of stations without one - including the current one which is
1500 watts. It just depends on the location how things work out.

1155. FT-50R first impressions

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-20 00:00:00 UTC
From: dddavis@atl.mindspring.com
Message-ID: <4l9lj4$sja@mule2.mindspring.com>
Source record: 202435

I just received my FT-50R dual band HT and am very happy with it. I won;t say much about physical dimensions, etc. since it is the same as the FT-10/40 which most have seen. I have gotten good reports on transmit audio, and the receive audio is very good as well. The only physical difference wirth mentioning is that the SMA connector is reversed from that on the FT-10/40. Thus, the Comet SMA-3 will fit. I don't have any good reason to do that, though. The supplied antenna seems fine and is 2" shorter. Also, the antenna has a sort of shroud which goes into the radio and seals.

I have discovered one "bug". If the APO feature is on, you cannot select a PL tone in VFO. Note you can turn tone on and off, but you cannot select what it is. This feature works fine (as described in the manual) when APO is off. It's an easy problem to work around, but potentially confusing. Luckily, I had used the feature prior to turning APO on, so I knew it would work and I just had to retrace my steps. I would have been baffled if I had started out with APO on. If someone discovers I am doing something wrong, let me know or post a correction.

All in all, a VERY nice radio. The high power version was only $10 more than low power, so I bought the HP and an additional low power battery. I'd love to see mods to open receive into the 50 MHz and 220 MHz bands.

One other small thing: I tried to receive a broadcast FM station (several in fact) using the wide FM setting. The signal, though strong, was distorted as if wide FM was not quite wide enough. (I did verify that I was set for wide.) Any comments? Don (KE4KYO)

Source record: 202438

Is the new Yaesu FT-50R HT available yet?
Does it do crossband repeat?
Does it have a wideband TX mod like the single band versions?
Looks like a cool radio for its small size, milspec, and DCS capabilites.
First impressions?

Thanks
-Chris

1160. RAC 'n Rollup Q&A #3

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-20 00:00:00 UTC
From: steve.hajducek@bytewise.org
Message-ID: <127.8913.27@bytewise.org>
Source record: 202440

Subject: RAC 'n Rollup Questions and Answers
Date : 1996 - Fir. Apr. 19 18:20 Local/ Sun. Apr. 19 23:20 Zulu
From : Steve Hajducek, N2CKH
TO : ALL RADIO AMATEURS

The following are some of the most common questions and answers regarding RAC 'n Rollup that have been exchanged via internet e-mail during the last week.

Q: Will be able to order both the Callbook CD-ROM and your RAC 'n Rollup program together ?

A: No, I only sell RAC 'n Rollup. However it is readily available from many sources, with the lowest price I have seen being $39.95 U.S. from AA6EE at 16832 Whirlwind/DX10, Ramona, CA 92065 as advertised in "The DX Bulletin".

Q: Does your program work with the revised version of the CD Callbook as advertised in the May QST on page 190 ?

A: Until I received my QST I did not understand this question. The answer according to sources at Amateur Radio Callbook is Yes. I have been told that the "REVISED CD-ROM" has added Country names and Date of Birth to the data and that the .DLL has NOT needed an update. Furthermore, I was told that the new version will not be available until mid May '96 for deliveries. Not having the revised version to work with I can not make and statements other then the fact that some entries in the November version had Country data, and to use those entries with RAC 'n Rollup you simply turn Prefix off or click on the next space in the country list box. Obvisouly with the revised version you would turn Prefix Off.

Q: I see Radio Amateur callbook advertising a revised version of their CD-ROM that has country information and label printing, can I get my money back for my RAC 'n Rollup order I just mailed ?

A: Yes. But, you already have the November version of the CD-ROM, why go buy the same data again for another $50.00 when for $ 9.95 you can use the version you already have ? Furthermore, RAC 'n Rollup is not only the answer for everyone that already has the first version of the RAC CD-ROM callbook, it has and will have additional features that enhance the use of the Callbook in both the current version, this "REVISED" version and future versions.

Q: Where can I get the demo version of RAC 'n Rollup ?

A: The file name is RAC_DEMO.ZIP and is 1.3MB is size and takes about 5 minutes at 14.4KB using Zmodem protocal. At present it is

available from the support BBS at 1-908-363-2760 and both the ARRL and Kenwood BBSes. I have also begun the process of putting a WEB site up, within a week or two I hope to have it in service.

Q: I liked the demo, but how come you do not provide grid square for overseas calls ?

A: Because the coordinates for the stations are not in the database to perform the calculations with. However, RAC 'n Rollup v1.0.1, which is currently being developed will add bearing and distance for both domestic and foreign stations, improved printing support for Laser, Ink Jet and CoStar printers and many other features.

Q: Your help file for RAC 'n Rollup makes mention of you CATCC software for radio control and logging, when can I buy this software and where can I get the demo and tell me more about it, does it do more then change mode and frequency ?

A: This is not a RAC 'n Rollup question, but since RAC 'n Rollup came from code written for CATCC it's only right to give CATCC some attention (I will get carried away) in this forum... so here goes:

CATCC is still under development. It is being beta tested officially by a number of Amateurs in the U.S. and abroad.

The CATCCjr demo that was released into cyberspace in October '95, which is an early version (May '95) updated for Kenwood radio support has acted as a widespread beta test program. Originally there was to be a version of CATCC for each major brand of radios, then the design developed features that necessitated one version of CATCC supporting all radio brands. Considering the level of support of the radio, not just HF but simultaneous HF and VHF/UHF and even multiple radios, with transverters as required, supporting 8 com ports at one time, you can see why CATCC has been in development and beta testing since January 1995. There is nothing else like it on the market.

The demo version (CATCCjr) will be on my WEB site as soon as the site is activated. The demo is now available from the ARRL BBS and my support BBS at 1-908-363-2760 and had been (may still be) on various amateur radio ftp sites worldwide, such as ftp.qrz.com and demon.co.uk and is over a 3MB download.

CATCC does so much more than just change mode and frequency when if comes to radio control that all other software that has been on the market stating "provides full radio control" will want to go and hide. Don't get me wrong, CATCC is not the perfect software for radio control, logging and award tracking, NOT YET! It does however excel at radio control and provides unique features found in no other radio control/logging software yet seen. The demo version is an adequate tease, very functional for radio control of Yaesu and Kenwood radios, simple logging to CT(tm) compatiable file format for importation to your current logging program (should you have one) if you want to just use if for station control. The software is highly integrated with the

real-time data from the DX-Cluster, it provides user programmable DX alerts with alarms and automatic response modes for grabbing spots, a DX Personal Information Manager for preprogramming upcoming DX expeditions and contests from Magazine, News Letter and Packet DX reports well into the future, with up to 20 callsigns or prefixes for each day programmble and automatically loaded at program start of UTC day change so that you never again receive a copy of the DX Bulletin(tm) or CQ Magazine (tm) and forget that DX expedition or Contest when the weekend rolls around, DX voice announcements, DX activity graphs, DX oprating habits tracking and analysis and more tools that help the user achieve DXCC success.

There will be two versions of CATCC release, the first will be full station control and logging to the user choice of compatiable logging programs database formats. The full version will provide its own database logging format and full report generators, award tracking etc. Thus if you are already a long time user of one of the major logging programs and want to keep using it for maintaining your database you can use CATCC/Lite for your station control and logging and the other software for reporting or make the switch to the full CATCC. Currently CATCC supports the following hardware:

Yaesu, Kenwood, Icom and Ten-Tec radios, both HF, VHF and UHF models where exist. JRC and SGC support is forthcoming. AEA MM-3. All the parallel port devices such as voice keyers, switch boxes etc. W9XT voice keyer. All standard packet TNC's. Hy-Gain DCU-1 and SARtek-1 (PDA Associates) antenna rotor controllers, with others under development. For callbooks we support Amsoft, Buckmaster, Radio Amateur Callbook and QRZ.

CATCC will go for $ 49.95 without printed manual and $ 59.95 with, and CATCC/Lite will be $ 29.95 without any printed manual offered. Both will also have shipping and handling costs as well.

RAC 'n Rollup now shipping and is only $ 9.95 U.S. plus $ 1.50 U.S. shipping/handling in the U.S. or $ 5.00 shipping/handling overseas.

Send your orders with Callsign, e-mail address and mailing address to:

I haven't used either of these rigs so the information I have is
second-hand. However, what I hear from many folks is that the Omni V
has a *slight* edge over the Omni VI for CW. I believe this is
because the Omni V uses all solid-state switching, whereas the Omni VI
uses reed relays to switch the antenna at the receiver front end.

On the other hand, I was recently told that the Omni V does not have
an actual RIT control, and that the funciton is implemented in an
awkward manner through the buttons that set RX/TX offset. Apparently,
this oversight has been corrected in the Omni VI.

Perhaps other readers who own these rigs can verify whether this
is accurate information.

>did not address many of the items mentioned above.

I have an Icom IC-820H and have been 95% happy. It has an excellent
reciever. I have been given very good reports regarding my audio. Of
the three radios you mention the 820H is probably the most convienent
to use mobile or as a rover if you are a contester.

The disadvantages are.... no RF gain control, both bands cannot be
scanned at the same time, and some of the controls that should have
been on the outside of the radio are on the inside...(such as a small
pot to adjust low power level).

My plan in the future is to wait and see what if any new allmode
muilti-band rigs Kenwood and Yaesu are going to offer in the near
future... they are about due. If there are no new offerings... I'll
use the 820H mobile. and get a TS-790 for home use.
I don't do satellite work only weak signal.

All the interface stuff in the 820H is the same as the 970 by Icom.

Hope I was of some help.

Brian Gaff <briang@bgserv.demon.co.uk> wrote:
> A Binary so short was OK, though mot encouraged on a non binary group ...

The real kicker is that it wasn't even a binary - it was a simple text file, uuencoded to either inflate its size or hide its true nature. Additionally, it was irrelevant to the original question (which asked about the non-U.S. model), described unsoldering the antenna (which is unnecessary), and gave the wrong frequency for testing.

> ... but I got 6 copies of it here. Better check your software!

Sounds more like someone trying to jam the newsgroup.

1165. TS-870 given Bad Report in Rad.Com review

Newsgroup: rec.radio.amateur.equipment

Message-ID: <cgAroDAPeQexEwN4@jmsknars.demon.co.uk>
Source record: 202445

I was planning to buy the new TS-870 until I read the Peter Hart review
in Radio Communication April 1996. He stated that the "close-in dynamic
range was particularly poor"
As my main band during sun-spot minimas is 80m, the DX end, where QRM is
at its worst, this poor close-in signal handling problem sounds pretty
damning

Has anyone out there any experiences with this transceiver that can help
me in deciding whether to buy or not

The weak signal ssb parts of the band can be LOADED with strong signals during a contest or unusual band opening. Those of us who hang around 144.200 know what I am talking about. I have missed more than one badly needed contact with my Yaesu because I was trying to copy a weak signal while my receiver was being trashed by a strong signal 20khz away!!
AA9DL and KC9DX - fellow 2 meters ssb'ers have confirmed the same with their 736r's. Luckily you don't experience this way down low where you hang out. Good luck on the eme. --- Steve N9ROU

From: k5qq@aol.com
Message-ID: <4lb6dk$sbp@newsbf02.news.aol.com>
Source record: 202448

Hi Carl

I am packaging my 706 up today to send back.

2 Meters has full 10 watt output and 6 meters has full 100 watt output but the rest of the bands vary from zero on 40 to 30 watts on 10 meters and the rest are 3-10 watts out.

Not sure what to make of it, but something is wacko. I also noticed the current draw dimishes on some of the bands with reduced output but on others the current pulses. I was using a small deep cycle battery that was not fully charged, so the voltage was down a bit.

Anyhow, if you figure out something, let me know. I thought about trying to call Icom, but I can never get thru on their line and I suspect they will just tell me to send it back.

Please send me any good hints you might get Thanks

1172. Comments on Yaesu FT-8500

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-20 00:00:00 UTC
From: lui@netcom.com
Message-ID: <lui-1804962313110001@192.0.2.1>
Source record: 202452

I'm looking for a 70cm mobile radio w/ alphanumerics, and the Yaesu FT-8500 seems to be the only radio which fits the bill. I can consider a Bendix/King or Motorola UHF commerical radio, but I also wanted VHF capabilities.

Does anyone have experiences with this radio and the programming software? Which microphone do you use? Any other radios, or future models, which may also meet these requirements?

The FT-50R and FT-3000M both offer 800-900 MHz RX (less cellular). Perhaps Yaesu will come out with a "FT-9000" with this feature too. More characters (>6) for the alphanumerics would really be nice too.

Icom offers the IC-2000H and Yaesu offers the FT-3000M, both with alphanumerics, but both only TX on 2m.

I have a RC85 controller that has been damaged by overvoltage caused by a
bad requlator in the RC85.
There may be several ic's that are damaged. We tried to trouble shoot
ourselves but it is more involved than our understanding of the unit.
I have talked to Link Communication in Montana, the company that bought
out ACC but they do not make repairs nor do they have a suggestion on who
to send it to for repair.
I would like to find someone who is experianced on the RC 85 to look it
over and see if it is cost effective to repair the unit.
If anyone has a suggestion I would appreciate your help.
Please send responce via e-mail.
Thank you for your help!

I'm having a ball with the FT-50. It is a dual bander, but not a twin band, i.e. you can only hear one band at a time. But, it has a tremendous wide receive coverage, much like a scanner. Very hot throughout the range, 100 memories, battery voltage meter, five watts output, excellent audio, etc.
Only gripe I have is that tone scan is an option, but otherwise the radio has just about everything. Price is great too, about $330.

I know something of the ACC systems...being a long time RC850 owner and
having all manuals on the RC 85s since day one...

What does it do and NOT do right now?

What regulator failed and what was the input voltage at the time of the
failure? Was it lightning or something else that caused it?

John M Sonley wrote:
>
> I was planning to buy the new TS-870 until I read the Peter Hart review
> in Radio Communication April 1996.

In my experience the RadCom review is accurate. If you're a serious contester in the major worldwide events you'll have problems. If not, you'll probably never notice anything.

Although the 870S uses digital filtering, it also has conventional crystal and ceramic filters in the 8 MHz and 455 KHz IFs. The narrowest conventional filters are 3 KHz. I replaced the stock 3 KHz filters in my TS870S with 8 pole 2.1 KHz crystal filters in both IFs from International Radio in Florida.

I had previously used the same filters in both a TS830S, a TS830M (same as the 830S but with the addition of AM, and no provision for CW filters), and the 455 KHz filter in a Yaesu FT990. Athough the 830M had no CW filters, I found that the combination of high quality 8 pole crystal filters and variable bandwidth tuning gave me all the selectivity I ever needed for CW contests. I had previously used Kenwood's 500 Hz CW filters in both IFs on the 830S, but found them too narrow for CW contesting because I missed stations calling off frequency.

In the 870S the International Radio filters give a marked improvement. I can't say how much, but I have done a direct comparison with an unmodified rig and it's worthwhile. They are automatically switched in when you select a bandwidth (the difference between your selected low and high cutoff frequencies) of 2400 or less.

One other observation. I used my 870 in an International Marconi Day station this weekend. We had two stations using separate wire antennas which were physically close together. When one station was transmitting on 80m, both a TS940S and an FT990 on 20m suffered from serious breakthrough and were unusable. The 870S was completely unaffected because its internal auto-ATU also works on receive and gave the necessary additional isolation.

Finally, if you enjoy AM listening, whether on LF of HF, there's nothing to touch the 870S for audio quality. It's a pleasure to listen to. On SSB also, as conditions permit, you can increase the bandwidth and hear SSB sound like it never did before.

Every radio is a compromise in some respects. You can't have the best of everything in a single rig. Because I do a lot of contesting, I had been thinking of selling my 870S, but now, and especially with the "new" filters, I've decided to keep it.

73,
Paul EI5DI

PS: The inbuilt keyer (same as the Super CMOS II or the Logikey) is the best available on any rig.

:>
:>IF this is about the MLA2500 conversion, what a waste of bandwidth.

This is about the article by W6TC in the April QST (The 811A: Grandfather of
the Zero Bias Revolution). The original poster contends that the article
represents a shameless plug for Svetlana tubes based on the last section
(two paragraphs).

I've known George Badger for several years. The article is a very good history of zero bias tubes and, yes, being the marketing person he is, George just couldn't resist the chance to get in a plug for his products.

:>IT IS GREAT THAT QST IS CARRYING SUCH MODIFICATIONS AND EQUIPMENT
:>CHANGES. I would not call this an upgrade to a MLA2500!, The single
:>800 tube is far to whimpy to two 8875's that I'll not be rushing out
:>to change mine out. I'd like to hear about the 1600 tube mod.

I would be interested in hearing W8JI's take on this modification. However, the Svetlana 4CX800 should do a very nice job replacing a pair of 8875s. The 4CX800 has th same plate dissipation capability as the pair of 8875s and if the cathode has sufficient emmission (enough current capability) it should be a good candidate to replace the very expensive and very fragile 8875s.

Robert Wood wrote:
>
> Anyone know the tubes inside a SWAN 1200Z?? # of? power?
> 73 Robert WB5CRG

Hi Robert-

I can't say about the "Z" model, but my Swan 1200X runs four 8950 sweep tubes and I have measured 600 watts PEP RF output from it, into a 50 ohm load. I know there were several iterations of the 1200 linear amp, and I think some ran 6LQ6 tubes.

It's a good amp. Very small and portable. The main thing I am constantly tempted to improve is the metering. The little edge reading meter on the front panel is all but useless.

I own one and have found the mod for extended transmit. It's the No. 1
jumper pad that you have to remove the solder from.(there is only 3 jumper
pads visible from behind the keypad. You are then able to transmit
vhf-140thru174 uhf-420thru469 mhz.

John:

I've owned an 870 since December, 1995 and have logged about 100 hours on it. Rarely have I experience the "close-in dynamic range" problem. I have noticed, however, that the receiver is quiet and very easy to listen to. I traded up from an 850S/AT and the 870 is light years ahead of the 850.

The 870 got an excellent review in QST several months ago, although they also pointed out the potential problem for close-in signal handling. Practically speaking, however, this is rarely a problem. I work about 50% CW and 50% SSB and have been somewhat active on 75 meters at night.

There's a good war being waged right now between the Kenwood 870, Yaesu FT-1000MP and the ICOM 775. I've yet to talk to anybody with these radios who's regretted their decision.

Good luck with your decision, John.

>necessary spaces?

(Note, if your iron uses copper tips (it probably doesn't),
you can file them to shape, but if it uses plated iron tips,
filing will ruin them)

Yes, there are needle tips available. Weller has a series of
them for their soldering stations, including some that are
very long and skinny. The problem is that they are so fine
that there is very little heat flow. This means you have to
leave them in contact with the board too long, and can damage
board or components and still not get a good solder joint.

Weller also sells tips with a fine chisel point in 1/16th
and 1/8th inch widths. These are better. If you have room
to get a chisel face down against the joint, these will
do a good job. But on a tight board there isn't room to
get the tip down where you get good heat flow, and you have
to use just the knife edge of the tip, and that's almost
as bad as the needle point tips.

For surface mount work, however, you don't want to use an
iron at all. What you want to use is a static hot air
source. There are elaborate static hot air sources built
into some SMD rework stations from companies like Pace,
but the plain little Weller Pyropen *Jr* is just fine for
field repairs.

This is a wonderful little pocket tool. It runs off butane,
and has a series of different static hot air shrouds available
to suit different soldering and desoldering tasks. It even has
some regular fine soldering iron tips available for those times

when you need to work on thru-hole mounted parts. There's also a big brother, the Pyropen, that can be used with really big tips, suitable for soldering PL-259 connectors outside in the wind, but you'll find no use for that working on the innards of a HT. I keep one of each in my toolkit, and a spare refill can of butane.

If you don't have a lot of SMD experience, and if you've never worked with a static hot air source before, you should practice on some scrap. The techniques are different from what you are used to with soldering irons.

You'll need the Pyropen Jr, a good jeweler's loupe (I use an 8x B&L), a sharp pair of tweezers, some SMD solder paste, some wooden toothpicks, some clean solder wick, and a bit of modeling clay. The latter is to form a dam around the work to confine the heat to just the part you're trying to replace.

Lets suppose you've found a bad part in a SO-8 package that needs to be replaced. Use the clay to form a dam around the part so that the nearer solder joints of other parts are protected. I normally roll the clay between my fingers to form a thin worm and lay it directly over the joints I want to protect. You can use the tweezers and toothpicks to help you position and press down the clay.

Now select the proper shroud for the Pyropen Jr so that you'll get good heat flow over the part to be desoldered. With tweezers in one hand and heat source in the other, quickly heat the part until you see the solder melt, then lift it off with the tweezers. Some parts may have adhesive holding them to the board for their passage through the reflow machine at the factory. If that's the case, a slight twist with the tweezers as you lift will bring the part right up. Don't overdo the heat, no more than a second should be required even for larger SMD parts.

Once you have the old part off, clean the pads with the solder wick to prepare for the new part. Just press it down with a toothpick over the pads and hit it with the hot air source. The piece you use has to be *clean*, and you might want to keep some liquid flux around to help it out.

Ok, now you've got nice clean pads for the new part. Take a toothpick and put a tiny dab of solder paste on each pad, then use the tweezers to set the part in place. Don't worry if it isn't perfectly lined up on the pads. Now hit the part with the hot air source. When the solder paste melts, its surface tension will pull the part into perfect alignment, you don't need to poke at it. Now remove the heat and let cool. Remove the protective clay dam and

you are done. It should look like the factory's work
and no one should be able to tell that you've done a
repair.

1207. Radio Atlas 400XHF

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-21 00:00:00 UTC
From: pt2kd@tba.COM.BR
Message-ID: <01BB2F20.64186580@maq119.tba.com.br>
Source record: 202324

I'd like to have some information about the new radio transceiver Atlas 400XHF
Price with power supply and equipments, performance, and so for.

Thank you very much

Francisco - pt2kd@tba.com.br

1208. Johnson Viking Phone Patch Info Needed

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-21 00:00:00 UTC
From: wtpoe@ro.com
Message-ID: <4lcckf$ea2@news.ro.com>
Source record: 202325

I recently came across a Johnson Viking (Part No 250-46) phone patch with no information. It has 3 pots on the face (RCVR GAIN, XMTR GAIN, NULL). On the back it has a 3 conductor line with shield ground, 2 pin plug, and a terminal strip with the screws labled : L2, L1, SPKR, RCVR in that order. There is also a grounding lug. I would appreciate any information on this phone patch.

Thanks,

Wyatt KF4CHZ

>give my licence !!!

Roberto, reinstall diode D59 and do an initial reset on the radio
and it'll be back to ham bands only transmit. (HF anyway) If you
also need to restrict VHF transmit coverage, there are a series
of diodes that have to be present for various countries' band
plans. Get the Service Manual for the radio, all the diodes
are labeled as to country, and there are good board layouts to
aid you in locating where they go in the radio.

>Any suggestions?

Have you checked quick set mode Q1? This allows you to set the power output to any value between 5 watts and 100 watts. This setting applies on a *band by band* basis. Make sure it is set to 'H' on each band.

Yeah, the tube amp will have much higher THD. That's why rock
guitarists like them so much, really incredible distortion
effects. Of course that's *not* what you want in a high fidelity
audio system.

>I disagree, while the TS-790 left some things out, it is still a good
>satellite rig.

The TS-790A has some horrible defects that make it unsuitable for satellite operation. The most brain dead feature is that the narrow filters don't work in the sub-band receiver, but that's the one you have to use when operating satellite because only the main band unit transmits. Thus your SNR suffers severely unless all you operate is SSB.

And like all other Kenwood VHF+ gear, it has absolutely horrible thermal design. The PA modules get very hot. The 70cm module in mine cooked out after only 30 days of operation (and Kenwood took months to fix it). The replacement PA module was worse. Instead of 18 amps current draw for 27 watts output (yeah it didn't meet power output specs from the factory), the replacement PA drew 22 amps for only 22 watts output. Then the 2m PA module died. Same problem, thermal cookout opened metalization in the module. I sawed that one open rather than send it back to the factory again, and fixed it myself.

And then there's the brain dead user interface. To make sattrack tuning work, you have to depress and *hold* the SAT button. That makes tuning a two handed job. And if you release the SAT button, you have to press it *twice* to get back into track tuning, useless. I rigged up a mechanical clamp to keep the SAT button depressed all the time.

I finally managed to unload it on a sucker (hi Brian), and got a real radio, the FT-736R. It runs cool, the narrow filters *work* for satellite, there's a for real rotary switch that puts you in sattrack tuning and *leaves* you in sattrack tuning, etc. In other words, it works right.

I know, I should have known better than to buy a Kenwood. I've got enough experience with them to know that they are all terminally brain dead. I just have to plead temporary insanity when I bought yet another of their poorly designed pieces of crap. (Hope springs

eternal that they'll finally get *something* right on a VHF+ radio.
Their HF stuff isn't half bad.)

In article <4l3q9n$jiu@nj1.n-jcenter.com> Mitchell <mitchell@n-jcenter.com> writes:
>I recently acquired my General ticket and am debating on a
>good first-time HF rig... Price is important, but features and
>quality are also essential. Should I consider a portable,
>like an ICOM IC-706, Alinco DX-70T, or a lower priced table
>top ICOM or Kenwood. What are some good used models to consider?

The IC-706 is a neat toy, and so small that it practically
disappears in the smallest vehicle. It's good, but it is not
a perfect radio. The receiver will crunch under strong signal
attack, and you need to mod it to get satisfactory out of band
receive on VHF. The Alinco's receiver is a little better in the
crunch department, but its IF filters aren't, and it only puts
out 10 watts on 6m if that's important to you. Yaesu's entry
in this range is better, but bigger. Avoid the TS-50, it doesn't
offer you anything the others don't do better.

If the ultimate in small size, and DC to daylight coverage,
isn't important to you, there are better pure HF radios out
there. One of the best buys is the IC-735. It had the longest
production run of any amateur transceiver, and it is still a
competitive performer today. You can find them on the used
market for around $650.

On the new market, look at the mid and top line Yaesus.
They're very nice. The current bottom and mid-line Icoms
and Kenwoods are not in the same league, though both
of those companies' top of the line radios are pretty good.
(Be really wary of used Kenwoods, however, there are some
real dogs floating around, especially certain TS-440s and
TS-120s. And you want to avoid IC-745s, they were real
crunch boxes.)

Ten-Tec also offers some good HF radios, though I don't
think their Scout is a good deal when you total up all the
costs to get it to cover all the HF bands and fit it with
a noise blanker, etc. It's still a kludge. Ten-Tec's top
of the line is very good though, and a used Corsair II might
be a good buy if you can find one.

Buying a used radio can be very smart. If you choose wisely,
you can resell it for about what you pay for it when you
decide you want something else. Any new radio is going to
cost you a big depreciation hit when you walk out the door
with it. Of course you have to be a little bit careful when
buying used. You have to know something about the model

or else you might be buying a dog. But on the other hand,
lots of people will have experience with the model and can
offer you advice about it. Other than just having to have
the latest gadget, buying new doesn't get you much except
a warranty, and that's usually not worth the big depreciation
hit. Some of the older radios had as good (and in a few cases
better) RF performance than some of the newest radios. So
buying used doesn't necessarily mean accepting second best.

>I don't have a mega-buck tube amp, but it's not for lack of trying. I
>first heard the difference years ago, but too late to pick up a
>McIntosh or even a Hafler-designed Dynaco at a reasonable price.

I had a pair of McIntosh 75s, and a Dynaco kit before that. They
were nice in their day, but their day is past. Their damping factor
doesn't match modern speakers, and THD and clipping was not pretty,
even on the Mc with its heavy negative feedback. Of course the old
Bozak Concert Grands and Altec Voice of the Theatre speakers had so
much distortion anyway that it was hard to identify the part contributed
by the amp. Even good modern speakers typically have 3% distortion,
and that's lots more than even a cheap amp produces unless it is
grossly overdriven.

>Incidentally, I wasn't kidding about the tests. At one time, I did
>double-blind A-B tests over and over because I didn't believe it
>either. We tried all kinds of tube amps, from the lowly Scotts and

>(Class A), Ampzilla, Yamaha and the better Harman Kardons. After a
>few minutes of listening, I was *consistently* able to tell the tubes
>from the transistors.

Yeah, me too, the tube amps had more distortion. You could see it
on a scope, and hear it in good headphones. You didn't usually
notice with speakers unless the amp was badly overdriven, however,
because speakers have so much more distortion. The best I've ever
heard was a pair of Martin Logan's driven by a 1 kW amp (tetrode
tube type actually). The Martin Logan's are pure electrostats, and
the amp had enough headroom to stay out of clipping. A Crown DC-300
amp sounded about equal, however, and I couldn't tell which was which
unless the music had a lot of very loud transients that drove the

smaller amp into clipping.

Music has a huge dynamic range, and most people try to reproduce
it with amps that are too small. If you need 40 watts average to
fill the room, you need about 800 watts peak to stay out of clipping
on transients. You *can* hear that clipping.

The other thing you can hear is the effect of improperly matched
damping factor. Tube amps offer little damping while transistor
amps have a lot (due to their very low output impedance). So if
you are listening with speakers designed for the damping factor
of one, the other will definitely color the sound. Modern speakers
(other than pure electrostats which are insensitive to damping)
sound boomy when driven by tube amps while older speakers designed
in the tube era are way overdamped when driven by transistor amps,
and have muffled bass.

>pot" and so on don't address my concerns, and neither do other general
>"well I think other people have done it" responses. So someone help me
>with facts, not feelings.
>
>Let me once again clarify... I have no objection to the first part of the
>article, the part I think is self-serving bunk is the section "The Next
>Revolution-High Performance Tetrodes'. Without that section, the article
>would have been very well written, unprejudiced, and truthful.

I think the article was as well written, unprejudiced, and truthful
as an article of that type can be. The "Next Revolution" section
explains the demise of the old 4 811A amps and the rise of the
more linear, higher efficiency, single tube amps that have replaced
them in some better amplifier designs.

>And hence my main point. Can anyone address these questions?
>
>1.) Tetrode PA's are more difficult to operate, construct and design that
>GG triode amps, the author's contrary statements were technically false.
>Please explain why tetrodes were incorrectly described as a new
>"technological reveloution" and listed with advantages they (in fact) do
>not have?

Tetrode amps have better linearity and more power gain than triode
amps. They do require a screen supply, and the tuning is a bit
different, but that's only marginally important when contrasted
to the advantages they offer. Tetrode amps were almost exclusively
used (before transistors took over) in TV transmitter linear PAs
because of their better power gain and better linearity. Even in
Class C FM transmitters, tetrodes were often the choice because
their higher power gain improved overall transmitter efficiency.

>2.) Why were tetrodes even mentioned in a article about 811's? What do
>they have to do with 811 tubes?

See above. They were mentioned to show the trend in amplifier design
thinking away from the older 811A multi-tube designs and toward the
single tube designs that have largely replaced them. Zero bias triodes
were also mentioned as another path away from the 811A. This, as in
mention of the tubes that preceeded the 811A, serves to put the 811A
in a historical context.

>3.) Why were the references (with the exception of one to an out of
>business company) only to other articles supporting the author's sales of
>tetrodes and to the author's company?

Probably because there's little literature to reference about power
tubes other than from the author's company and Eimac still available.

>4.) What technical or historical function does any of this have, other
>than to promote the author's tubes over triodes?

Historical context. The 811A is obsolete as a power amplifier tube
except in a few retro designs. Mentioning the two main contenders
which replaced it is certainly a good way to show why the 811A
passed from the scene for new designs.

>> It told more of a story about Eimac and RCA than about anyone else,
>>the Russian bottles came over as simply copies of the originals. If
>>someone from Svetlana can write in public in such a way, where their
>>competitors are favourably treated, then I am pleased.
>
>But they didn't do that. They directly painted Eimac's zero bias tubes, in
>the closing section, as "not driven by technical performance" and "driven
>by simplicity, low cost, and Eimac's superb promotion". They inferred the
>Eimac tubes are old technoligy.
>
>That is either self-serving criticism of another competitor or it is a
>simple technical fact. Since it is not a true technical fact, it must be
>self-serving propaganda. Someone please correct me if I've made a
>technical error in this. I want to be fair.

It is technical fact. Eimac's zero bias triodes are the result of wanting
tubes that can be used in simple and low cost amplifiers. You claimed as
much above when you noted that they allow amplifiers without a screen
supply (or a bias supply). They are not driven by technical performance
since they don't have either the power gain or the linearity of tetrode
amplifiers.

The popularity of triodes in GG amplifiers for amateur service is
driven by the FCC limit on power gain in external amplifiers for
HF Part 97 operation, the lax distortion requirements for amateur
HF linear amplifiers, the wide availability of 100 watt class
exciters, and the lack of skill and knowledge among amateurs
as to the proper tuning and operation of power amplifiers, IE the
tune for maximum smoke syndrome. At VHF, where higher power gain
is usually wanted (and permitted), where a stricter linearity
standard is imposed, and where the skills of operators using high
power tube amps is usually higher, tetrode amplifiers are almost
universally used.

If you want to argue that triodes are technically superior to
tetrodes, I think even Eimac would take exception since they
wrote the book on power tetrodes. And don't forget that Svetlana
makes triodes too. Are you accusing the author of denigrating

his own products as well?

I really don't understand why you are upset about this article.
It seems as if some personal ox of yours must have been gored
for you to raise these ill founded objections to the article
so strongly.

For Sale:
Harris RF590 0-30Mhz receivers. Very clean, used by the US Dept. of
State at the local US Consulate here in Jerusalem until very recently.
Side by side with my Yaesu FT-990, it beats it hands down in every way.
30dbm 3rd order intercept point, 100 memories, remote controlable, all
filters installed. One of the best receivers ever made (imho, along
with the Collins 851S-1A and Rohde & Schwartz EK-70).
I also have the matching exciters and Harris 1.5KW amplifiers with PS
units. All in very clean condx.

Make me an offer.

I can be contacted at:
011-972-2-785578
or e-mail me at:

1223. Kenwood DSP-100

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-21 00:00:00 UTC
From: Jeff Goebel <jgoebel@rrnet.com>
Message-ID: <317A2F7A.3BF9@rrnet.com>
Source record: 202340

I have noticed that the DSP-100 is greatly reduced in price. I own a TS-690 and am wondering if this is a worthwhile addition to make to the rig. Does anyone have any experience with the DSP-100? How well does it work? I currently have a Timewave DSP-9 but I rarely use it with my TS-690 because it tends to make the signals less pleasant to listen to. The voices have a unnatural ringing quality to them. It does reduce background noize though.

Anyway, how do the signals sound when using the DSP-100?

Thanks,

Jeff Goebel N0VHB

cardenas@kaiwan.com (Anthony O. Cardenas) shared the following
priceless pearls of wisdom:

>>I'm looking for information on crystal ovens.

>'Yo, Steve,

>Some companies are SO cheap, they use a resistor and heat shrink to
>keep the crystal at a semi-constant temp.

Actually, the design of a resistor/shrink/diode combination is quite
difficult and an elegant inexpensive solution to a complex problem.
It isn't just a resistor inside shrink if you do it right. All you
get there is a hot crystal that still responds to changes in ambient
temperature.

The trick is to put the resistor (actually just a heat source) on one
side of the crystal, a silicon diode on the other side of the crystal,
shrink sleeving AND silicone seal the ends, and then use the diode's
voltage/temperature curve (which is unbelievably repeatable from diode
to diode) to feed back the temperature of the crystal case to an
amplifier which then regulates the current through the resistor. By
the time you get through analyzing the time constants of resistor
heating, thermal resistance of the case, how long it takes the case to
heat the diode, then crank all that back into the loop's transfer
function, you've got yourself a day's theoretical work on your hands.

Of course, the way most of us do it is hook it up, measure the loop
time constants, then throw in an electrical time constant ten times
more than necessary. Yeah, it takes a little longer to settle down
than an exact analysis, but it won't go flegging off into thermal
oscillation at the drop of a quantum, either.

You can actually get control down to less than a couple of degrees
over the full ambient temperature range if you do it carefully enough.
It sure beats the hell out of those old bimetallic strips on the
heater ovens we used back in 'dem golden old days. You remember --
radios that glow in the dark??

1229. Johnson LTR stuff for Sale/Trade

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-21 00:00:00 UTC
From: ki5bd@aol.com
Message-ID: <4ldrcm$lt0@newsbf02.news.aol.com>
Source record: 202346

I have the following radios for sale or trade. All operate on the Johnson Clearchannel LTR trunking system.

Uniden FPS 820 TS handheld (the big one) with DTMF and APX114 rapid charger.
$175

Uniden FTS 800 TS trunk mount mobile with DTMF mic.
$200

E.F.Johnson 8870 trunk mount duplex phone/radio with TD7 paging feature.
$200

E.F.Johnson 8870 with Telephone Interface Module (allows the use of any standard telephone equipment). Great for remote locations where there is no standard phone service. It works like a standard wall jack and allows the use of multiple phones, fax machines, modems, cordless phones or alarm equipment.
$400

All of these units would require programming by your local E.F.Johnson LTR provider.

Add $20 each for shipping.

Will trade for All Mode Dual band 2m/70cm rig or other ham stuff.

Resond by Email to : KI5BD@aol.com

1232. RE: Beldon 9913

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-21 00:00:00 UTC
From: mattro@radware.net
Message-ID: <N.042196.122651.62@ppp0014.radware.net>
Source record: 202349

My experiences with 'real' 9913 taught me never to use it again. There are many cable types which offer _almost_ the same electrical/RF specs, which at the same time are much easier to use mechanically. 9913 is hard to work with due to the way it is built. The solid center is a
major concern. It makes the cable hard to route and manage. Also the air core makes the cable easy to 'kink'. I suggest using a good quality RG-213 with a stranded center, solid dielectric, and 97% or more braid. If you don't mind a little more $$$ the foil+braid combination seems to work well.

The Atlas company has failed again. The remaining assets appear
to have been turned over to another company, but those having
deposits on the Atlas radio will probably never see either their
money or a radio.

Hi Mike, to exist, abstract numbers require a being capable
of abstract thought processes. Assuming man is the only
being capable of such, numbers didn't exist before we
did. That means they exist only in our minds. Does that
make them real? I think, therefore I am? I doubt it. More
likely, it's "I am, therefore I think" or as Ayn Rand and
Aristotle put it "A is A".

I have a UHF Radius (PN: D44LRA7PA5CK) I would like to move to the Amateur 440 band. Is it possible to program the new freqs in w/o doing any tuning?

Has anyone done it before?

Thanks.

1252. Intrinsically safe certification

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-22 00:00:00 UTC
From: saremington@imt.net
Message-ID: <4lf08p$4rl@cu.comp-unltd.com>
Source record: 202289

Thanks to all who answered my question on type acceptance. The answers were quite informative. Now, another question:

Can anyone explain intrinsically safe certification as its applied to radio equipment? I kind of have an idea that to be certified, the electronic device must be incapable of generating a spark that could cause an explosion. I'd be interested in the specifics of what testing is done and why.

Thanks in advance.

I am selling a PK-232MBX in great conditon! This TNC has Packet, Morse Code, Baudot, ASCII RTTY, WEFAX, NAVTEX, and AMTOR/SITOR will do PACTOR with upgrade. Also, has 2 ports can handle HF/VHF. 18k Mailbox inside and plenty more....

Have manuals, cables made up for Kenwood TS450 if you have this also have premade cable for Kenwood HT. If you have another radio I have plan cable for you to make your own cable for your exact radio. Might even have the box... will have to check though!

If interested I am selling it for $175 + shipping.

Email me at N9MXT1@AOL.COM
For more info call me at (847)824-2112 Home
(847)824-2235 Fax number

Thanks for your time and hope to hear from you

1255. Kenwood TM-241 mod - HELP!!!

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-22 00:00:00 UTC
From: usdhicks@cc.memphis.edu
Message-ID: <1996Apr22.001246@msuvx1.memphis.edu>
Source record: 202292

Thanks for reading this.

I would like to mod my Kenwood TM-241 2mtr mobile rig for expanded transmit (153 Mhz for RACES). I cut the green wire loop coming off of the display, but that only opened it up to 151.995 mhz. All the mods I have been able to find say to put a 1N914 diode across D209, which is behind the tone button. But there is already some kind of chip across D209, and when I install the diode, nothing happens. This mod worked fine on my older TM-231 because there was nothing in the way. But this chip on the TM-241 seems to have an effect on the mod.

Does anyone have any ideas?

73 & thanks,
Steve

What Bob Weir and others seem to have failed to mention is just how bad the old octal plug-in bimetalic snap action thermostat ovens really were. Those old ovens cycled the crystal over 1 or 2 degrees C every few seconds. I can recall listening to the beat-note of a 400 MHz signal multiplied from such an oven. It sounded like a slow fire siren.

Paul,

I had been considering adding the IRCI 2.1 filters to my TS-850, but was worried that they
would be too narrow for SSB contesting. I already have a single 1.8, and don't like it
because the tuning is too touchy. It's hard during the heat of a contest to tune in those
that are slightly off my run frequency.

Do you find that the 2.1's have this problem? Is you hand constantly on the rit while
running stations?

Thanks

Intrinsically safe ratings are applied to electrical equipment that may be operated in flammable or explosive atmospheres. The ratings are for specific classes, groups and divisions which are essentially the type of atmosphere (flammable gas, vapor or dust) and whether the atmosphere is hazardous on a continuous basis under normal operating conditions or only during an out of spec operation such as a leak. The groups (A,B,C and D) are based on the burning characteristics of a representative gas or vapor, e.g. acetylene is group A, which are highly flammable materials. Hope this helps. 73 de Mark, WB9BVV

In article <1996Apr21.100318.5229@ke4zv.atl.ga.us>, gary@ke4zv.atl.ga.us (Gary Coffman) writes:

>It is technical fact. Eimac's zero bias triodes are the result of wanting

>tubes that can be used in simple and low cost amplifiers. You claimed as >much above when you noted that they allow amplifiers without a screen >supply (or a bias supply). They are not driven by technical performance >since they don't have either the power gain or the linearity of tetrode >amplifiers.

That's untrue Gary, and exactly what this article would have readers believe.

No "rule" makes tetrodes "cleaner" than grounded grid triodes. There are some types of tetrodes that have exceptionally low distortion, such as the 4CX1500A ....but there are also triodes designed for low IMD.

Point in fact? The exceptionally clean 4CX1500A tetrode and the standard 3X1500A7 triode have identical third order SSB IMD performance of -40 db.

>The popularity of triodes in GG amplifiers for amateur service is >driven by the FCC limit on power gain in external amplifiers for >HF Part 97 operation, the lax distortion requirements for amateur >HF linear amplifiers, the wide availability of 100 watt class >exciters, and the lack of skill and knowledge among amateurs >as to the proper tuning and operation of power amplifiers, IE the >tune for maximum smoke syndrome.

That's how Hams usually tune their tetrodes also, maximum smoke! Tetrodes are LESS forgiving of mistuning, require regulated supplies, are less compatible with Ham power level exciters, and offer no guarantee of IMD improvement.

>At VHF, where higher power gain >is usually wanted (and permitted), where a stricter linearity >standard is imposed, and where the skills of operators using high >power tube amps is usually higher, tetrode amplifiers are almost >universally used.

Untrue. The main reason is drive power and cheap tube availability, not IMD. The most common tube at VHF is a 4CX250 family tube. Third and fifth order products are only -25 dB down with this "clean tetrode". A 3CX800 "dirty triode" will produce -36 dB third and -42 dB fifth order products.

>If you want to argue that triodes are technically superior to >tetrodes, I think even Eimac would take exception since they

>wrote the book on power tetrodes. And don't forget that Svetlana
>makes triodes too. Are you accusing the author of denigrating
>his own products as well?

I'm not accusing anything. I'm speaking facts.

Triodes and tetrodes have almost identical IMD performance when the tubes are properly designed. As a general rule, triodes have superior performance in amateur type service. These are the true facts.

>I really don't understand why you are upset about this article.
>It seems as if some personal ox of yours must have been gored
>for you to raise these ill founded objections to the article
>so strongly.

Yet another personal comment!!!! While my objection is to the technical inaccuracy of the tetrode area of the article and to the use of the misinformation to directly promote the author's tetrode, the standard retort by people unfamiliar with the technical facts about tubes are usually similar to the above personal comment.

Let me make clear (AGAIN) exactly what my concerns are:

1.) Claiming Eimac's zero bias tubes were not "performance driven". There is no technical support for that statement. It must be the author's personal opinion since it is contrary to fact.

2.) Claiming tetrodes are some sort of "new revolution" in design. Tetrodes were around long before zero bias triodes became popular. Zero bias triodes became popular because:
a.) They were more cost effective to manufacture
b.) They offered superior performance in HF amateur applications
c.) The support circuitry was much lower cost and more forgiving of design and operating error.

3.) Using a free article in a membership journel as a marketing platform by making technically false or misleading statements.

Please don't "turn" my objection to technical or factual errors into something "personal". Personal comments have no place in a discussion of fact.

I might be able to help a little. I have no factory info but:
L1 & L2 are where you attach your telephone line.
I would guess that the 3 conductor connector is the output to tthe microphone.
I would guess that the RCVR connection tho be the audio output from your
receiver, with the SPKR connection going off to the speaker. Expect a common
chassis ground for the return side. The idea here is that you want thespeaker
muted when you are using the patch.

The RCVR gain will set the received audio level you put out onto the phone
line.
the XMTR gain will control the audio you put into the microphone input to your
transmitter.
The NULL pot is a bridge adjustment that affects the feedthrough from the
receiver audio back onto the microphone line. If you have a meter on the
patch,
you should be able to adjust the null something like this:
1. Tune a good strong hetrodyne on the receiver. 2. Call someone and instruct
them to lay the phone down for a few minutes. 3. Switch the patch on, and set
it to the null position. 4. Adjust the NULL pot for minimum output shown on
the
meter.

This should help.

I bought one last year at Dayton and sold it a few months later.
Good points - It's tiny!
Bad points - The low power output and lousy antenna make the radio
useful only if you are within shouting distance of the other
station/repeater.
Screw-on antenna, not BNC.
Manual is terrible. Whoever translated from Japanese nees some English
lessons.

Sri, but don't recall about toneburst...

>Yeah, the tube amp will have much higher THD. That's why rock
>guitarists like them so much, really incredible distortion
>effects.

Gary, this is completely untrue. Lead guitarists often run their amps "wide open" in order to imitate the sound of musicians like Hendrix and Stevie Ray Vaughn. The soft clipping of tubes produces an effect that cannot be duplicated with either a solid-state amplifier or external "fuzz" devices. Contrary to your statement, the tube amplifier produces less odd-harmonic distortion when driven into clipping, in turn creating a more "natural" sound.

>out here it's a lot of money so I want to get a rig that will
>last a while.

The FT900 has an internal autotuner and a receiver that is less
overload prone. The IC-706 has 6m and 2m plus wide VHF receive,
and is *much* smaller. If you don't care about 6m and 2m, and
if absolute size isn't critical, you may be happier with the
FT900.

The designers made different tradeoffs. I looked at both,
and bought the IC-706. I wanted the very small size, I wanted
6m, and having 2m too was icing on the cake. I don't care a
whole lot for internal autotuners, figuring that an external
tuner is usually more flexible. And I've learned to cope with
the overload problem (more frequent use of the attenuator),
though I'm still investigating ways to mod it to solve that
problem.

The FT900 is a fine small HF radio, but I'm keeping my IC-706.
You might choose to go the other way and I couldn't say you'd
be wrong. It all depends on which tradeoffs you prefer. I'm
also keeping my IC-735, and it's a better all around HF radio
than either of them (IMHO). A used one goes for around $650 and
might be the perfect upgrade from a FT101. (Note, I saw in the
latest AES catalog that they still have *one* IC735 demonstrator
for sale with warranty. It may be the last "new" IC735 in existance.)

Are you sure you had the EE model? Mine didn't even have a factory-
installed crystal for 11M. The TX lockout jumper was only used to
prevent transmission on the 10 MHz WWV band.

The facts seem to suppport your comments 100 percent Rob.

But I am more concerned with the technical inacccuracies presented. It is a much larger problem when fact are mis-stated to promote a product, even in a paid ad.

Technical articles should be based on fact, not hyperbole.

I am puzzled why more of us don't share that view.

I have not seen the article Joe. Do they regulate thee screen and grid
bias? How do they drive the tubes, cathode or grid? Do they monitor the
screen current and protect it?

By the way, thank you for the direct reply to my question. I suspected
there was a bit of "marketing" involved in the article.

Doesn't QST watch for that?

George isn't the problem, even though his plug included statements
that are wrong. The editors are to blame for allowing his technical
inaccuracies to slip into print.

Hopefully, no one will build a tetrode amp as a result of this
article, only to discover that what they really needed was a simpler
and cheaper triode design.

QST should print a correction to the statements in the article
relating to this point, and should probably apologize to Eimac as
well.

Very sloppy work.

Hi Bobby, my dad pays long distance charges to download this newsgroup
at 1200 baud. He lives on social security and doesn't want to pay for
for sale stuff. He doesn't download rec.radio.swap.

>Your Newsgroup address said HAM-EQUIP i seen nothing for
>Not Posting and FS Gear in this newsgroup.

The "Guide to the Personal Radio Newsgroups" is the FAQ for the
r.r.* newsgroups. It says not to post for sale postings here.

>How does one unsubscribe from this and ill be glad too look else where or
>start my own listserv for FS stuff.

There *is* a newsgroup dedicated to for sale stuff. It's described
in "Guide to..." and is rec.radio.swap Everything is already set up
for everybody. All they have to do is read the "Guide to..." which
is published on all these groups from time to time.

Almost every newsgroup has a FAQ or "Guide to..." Is it too
much to ask that everybody read it and abide by it? Individuals
violating the guidelines are killing the goose that lays the
golden eggs.

>I had a pair of McIntosh 75s, and a Dynaco kit before that. They
>were nice in their day, but their day is past. Their damping factor
>doesn't match modern speakers,

That's marketing nonsense, intended to cover up the fact that many "modern" speakers are junk. They employ ports and enclosures that boost undamped bass response, with no regard for the tuning between the enclosure and driver. Placing a loosely-suspended woofer in a two-foot tall box with a port helps sell speakers, but it destroys the damping of the driver below the resonant frequency of the port. It's unreasonable and totally unrealistic to criticize an amplifier for its inability to compensate for this. Even the highest damping factor you can produce won't remedy the problems created by these speakers.

>and THD and clipping was not pretty, even on the Mc with its heavy
>negative feedback.

Clipping isn't pretty in any amp. The difference is the way the two types of devices clip. Tube amps create less of the odd-order distortion that is particularly offensive to the ears.

>Of course the old Bozak Concert Grands and Altec Voice of the Theatre
>speakers had so much distortion anyway that it was hard to identify
>the part contributed by the amp. Even good modern speakers typically
>have 3% distortion, and that's lots more than even a cheap amp
>produces unless it is grossly overdriven.

High quality electrostatics, planars, horns, ribbons, the old Heil driver, and even some soft-dome midrange and tweeter drivers exhibit much less than 3% distortion.

>Yeah, me too, the tube amps had more distortion. You could see it
>on a scope, and hear it in good headphones.

If you could see it on a scope, I'm not surprised the results were disappointing. No good tube or transistor amplifier will do this unless it's driven to clipping or into an unsuitable load. In any event, many people disagree with your results and their claims have been verified in double-blind tests.

>Music has a huge dynamic range, and most people try to reproduce
>it with amps that are too small. If you need 40 watts average to
>fill the room, you need about 800 watts peak to stay out of clipping
>on transients. You *can* hear that clipping.

Where in heck did you come up with this? It certainly speaks in favor of tubes due to their softer clipping characteristics, but I've never heard a technically valid claim that 800 watts headroom would be required to eliminate clipping at average listening levels in the home. I'd like to see the math, including the sensitivity of the speakers in SPL at one watt/one meter, the size of the room and the SPL you consider "room filling" either at the location of the listener or one meter from the driver.

Also, which speakers are "most people" using that are capable of reproducing the 800 watts peak that you claim is necessary?

>The other thing you can hear is the effect of improperly matched
>damping factor.

There's no such thing as matched damping factor. It's a euphemism for the need to minimize the audible defects of junk speakers. I suggest that if you think older speakers such as Acoustic Research, Klipsch, Altec, University and Jensen have muddy bass when they're driven by solid-state amps, you've been conditioned by the large amount of crap that's now on the market.

>got enough experience with them to know that they are all terminally
>brain dead. I just have to plead temporary insanity when I bought
>yet another of their poorly designed pieces of crap.

Yes, Kenwood user-interface always sucks...
Quite some years ago, the local packet radio networking group bought
a lot of TM-531E 23cm FM transceivers to use for links in the Dutch
packet network.

They have to operate in a 59 MHz split for this, and it is unbelievably
complicated to set them up to do that... when you don't have a manual
with you when at a link site, you are basically lost when you have to
retune a transceiver. And sometimes they suddenly lose their memory
and have to be retuned :-(

ALL the Kenwoods (even the 790) are lacking a programmable repeater split.
You get what they think is right for your area. However, the split
has been changed a few times because of bandplan changes and coordination
with other band users, and now it is 28 MHz. That is not present in
Kenwood transceivers, so you can no longer freely tune around in the
repeater subband (you have to program each repeater in a "split" memory).

Also, the TM-531 has serial control via its MIC jack, which is proven
by the existence of a "remote control" from Kenwood. However, they
refuse to publish the protocol used. (unlike Yaesu and ICOM)
So, we cannot do remote control of our transceivers in the packet
network, which would have been very nice (to set power level, reprogram
the frequency when it has once again forgotten it, read S-meter value, etc).

There is also a bad bug in the design: they generate output even when
the PLL has not yet locked. This causes interference around the transmit
frequency. Setup a spectrum analyzer to store peak values seen around
the transmit band of the local node, and you see a 3 MHz wide spectrum
around the transmit frequencies. The interference is so strong that it
jams other links.
The 2M and 70cm units have the same bug.

Finally, they are not suitable for G3RUH modems, so we still run them
at 4800 bps using HAPN modems.

All in all it was a bad choice. The only advantage of these boxes has
been that they don't fail too often, especially when run at 1 Watt.
Unfortunately, there is no really better commercial alternative. The

only well-working 23cm link transceivers are the kits available from
Germany...

>
>73,
>Jack WB3U

The HR-1680 was a 100% solid-state receiver, made in the late 1970s. It was the companion to the HX-1681 CW transmitter. It covered 80/40/20/15/10m, plus (I believe) 15 MHz for WWV. There was no provision for an i-f filter, although there was an audio-type CW filter included. There was also no provision for a noise blanker. It wasn't a bad receiver for casual use, but like most Heath receivers, it wouldn't hold up under the grueling conditions of a contest. These are selling on the hamfest market for $50 to $100.

WHY don't YOU come off this bullshit juvenile thread and get a life? How many past articles would you suggest as reasonable that I provide from QST and other magazines to show that this is not really uncommon. QST is *NOT* a "newspaper*, or other similar publication with different standards of journalism - it is a magazine presenting material to a relatively narrow cross section of special interest individuals. Who would be better qualified to present a useful article relating to a specific facet of Amateur radio, some one well down on the technology ladder, or an engineer or manufacturer DIRECTLY involved with the element in question? This is *NOTHING* but senseless bitching!

1298. FT-50 Wide FM Receive

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-22 00:00:00 UTC
From: dddavis@atl.mindspring.com
Message-ID: <4lh3av$2dg8@mule1.mindspring.com>
Source record: 202385

I called Yaesu today to ask about the wide FM mode on my FT-50. I received email from one person that a Yeasu engineer told him that 25KHz filters were used instead of 75 KHz by mistake. Another respondent was told by Yaesu that the wide FM isn't "true" wide FM broadcast receive, but just TV sound (which works fine on my unit). That seems inconsistent with the sales info which talks about FM broadcast receive capability. The response I got was similar to that of the second caller - that WFM was not really wide. When I asked about the other story, the Yaesu employee said that, since the first radios are just now here, he wasn't really sure if things would be changed or not. I'm not too worried, since Yaesu has always "made things right" when there is a mistake (i.e. 15 KHz scan mod on the FT-51R). I guess it remains to be seen if this is considered a mistake in radio construction or in ad writing. anyway, FYI...

PS I like the radio very much and I will be glad I bought it even if I never use WFM. If you are considering purchasing one, don't let this scare you away. I'm very happy with it. Don (KE4KYO)

Source record: 202386

Hi Gary

I didn't know the setting of '1 thru H" for the power was kept per band so that is some useful information. However, to the best of my knowledge never did a lower power on HF than the max. I did set the power down on 2 m SSB so I could drive a small 30 watt HT type anmplifer that had SSB as one of the modes.

In any case, I also did a CPU reset and then I took the power measurements into a Bird Wattmeter with internal dummy load, so I don't think it's a setting problem.

But thanks for reading and replying. I appreciate it. (Of course it would be real aggravating to find the problem now that I shipped it off to Icom!!!)

Adios and thanks again

Jim

1305. FS -- KINGS PJ-068 MIC PLUGS << THE REAL THING >>

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-22 00:00:00 UTC
From: "Bill (AA4FM/0)" <debral@falcon.cc.ukans.edu>
Message-ID: <1996Apr22.223842.118418@kuhub.cc.ukans.edu>
Source record: 202392

:::::::::::::::: KINGS PJ-068 MIC CONNECTOR ::::::::::::::::

New original PJ-068 microphone plugs manufactured by
Kings Electronics.

These are the MIL-SPEC mic connectors supplied as original
equipment to the military and Collins Radio.

Why buy a cheap copy when you can have the real thing
for the same price?

Fits Collins, Drake, and others that specify a .206"
3-conductor phone-type mic plug.

These plugs retail for about $14 + postage (if you can
find them!)

My price: $7.50 each (I pay postage)

1306. Re: Yaesu FT-101E Bands

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-22 00:00:00 UTC
From: "Bill (AA4FM/0)" <debral@falcon.cc.ukans.edu>
Message-ID: <1996Apr22.223209.118417@kuhub.cc.ukans.edu>
Source record: 202393

The FT-101E was (and still is) an EXCELLENT radio for the money. If only those darn sweep tubes didn't keep creeping up in price!

I think that Yaesu knew exactly what they were doing when they provided the capability to operate on the Children's Band.

They were greedy! Why not make a buck? Let's add 11 meter capabilty! We can sell to U.S. hams AND CBers. We don't care! Just take the money and run!

I still have my 101E and use it when I'm not on the KWM-2A, but somehow I still feel a bit embarassed when I say "rig here is FT-101E". You know that it shouldn't be that way.

1307. FT736 MEM->VFO and PMS->VFO transfers

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-22 00:00:00 UTC
From: dgf@netcom.com
Message-ID: <dgfDq9vry.B60@netcom.com>
Source record: 202394

I've had a FT736 for a long time and always lamented lack of a key to copy memory to VFO. (there are multiple ways to write/destroy/mangle your memories, but no documented way to read a memory to VFO).

Anyway, thanx to an e-mail from Charles Sherwood sherwood@cig.mot.com, it turns out there are key sequences to do memory read, along with copying the current PMS frequency to a VFO.

MEM->VFO: Go into "MR" mode and dial to the desired memory. Push VFO A or VFO B button to select the VFO. Press F then VFO. Display will then show the selected VFO, and operating freq/mode will reflect the copied setting.

PMS->VFO: Go into "PMS" mode and scan/band to the desired frequency. Push VFO A or VFO B button to select the VFO. Press F then VFO. Display will then show the selected VFO, and operating freq/mode will reflect the copied setting.

I haven't seen reference to either maneuver in the manual. If it is in the manual, could someone refer me to the right page/paragraph, so I can kick myself for suffering for all these years? ;-)

Anyway, much thanx goes to OM Charles (chuck?) for solving one of the most aggrivating problems I have with the FT736. I didn't get his callsign.

T.A.P.R. makes a unit that fits into your external speaker that you can program to open with ctcss tones. It will trip relays and external devices. They do have a web page and the gaget is in the page. I have it in my bookmark if you want to address. T.A.P.R. are the people that founded packet radio.

1309. Info Request: Mobile Data Terminal

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-22 00:00:00 UTC
From: Desmond Crisis <dcrisis@cnet.com>
Message-ID: <317C5D52.3A08@cnet.com>
Source record: 202396

Hello and thanks for reading this.

I've recently acquired an MDT (pretty sure it's a Motorola) and I want to put it into service on a mobile packet station.

I don't have the model number of the unit but it is apparently a few generations old. (it has a dot-matrix style display rather than a CRT and a limited keyboard) The unit is all one piece and has a DB-25 as well as a similar style 37(?) pin connector on the back. Power apparently comes through the DB-25 somehow. According to the man I bought it from, the 37-pin connector (and board it is connected to) were not present on most of the units in the batch he originally purchased from a police department in either Nevada or Arizona. (Apparently the department replaced them with GRID laptops.)

I'm hoping that it will speak RS-232 somehow and that I'll find a way of mapping one of the special function keys to operate as a carriage return.

If you have any information on MDT's or pointers to more information I would greatly appreciate it.

Thanks,

Desmond Crisis

Message-ID: <4lfrql$57u@nw002.infi.net>
Source record: 202398

I'd like to thank everyone for their tips & advice on coax. I did find Belden 9913 locally for .59 cents/ft. plus $12.00 for the correct connectors.

What an improvement!! The local airport (15 miles away) ATIS is now receivable, never heard it with the RG 59 coax. Also the signal on 800 mhz + is much stronger.

Not to mention that Kenwood no longer sells parts for their own radios. They have opted to only sell parts through a third party vendor. I believe the name of the current parts vendor is Pacific Coast Parts or something like that. Be prepared for sticker shock when you order a Kenwood Part from them. I had a heck of a time when I called and asked for panel lamps for a Kenwood 7625. Not only did they not understand what I wanted to buy, but when they finally found the part for me, they charged me about $3.50 each for them.

How does this work, Jack? What is the effect of clipping, when viewed in
the frequency domain, if it is *not* the creation of odd-order overtones?

Hi Joe,
Thanks to you too for a breath of honest technical reasoning in a strangely emotional thread!

For a moment I thought the uni-bomber was here, hi.

In article <4lhoa6$7ck@ram2.ramlink.net>, subich@ramlink.net (Joe Subich) writes:

>Tom, the screen and grid are both regulated supplies. The screen at
>about 350 volts with voltage foldback as the current increases (to
>prevent the screen from dissipating excess power). The grid is also
>regulated (zener diode).
>
>The tube is grid drive with an untuned resistive termination (50 Ohms
>with a slight inductance by using a mix of non-inductive and wire wound
>resistors).

What is the grid bias voltage of the tube and the class of the stage?

I find it strange that all these tubes require a 50 ohm grid resistor to develop correct grid voltage swing with a 100 watt exciter. That almost seems too good to be true. I am trying to help three people get 4CX1600's running. One guy's amp only needs ten watts of drive! Of course many solid state exciters get trashy when turned down that far. A FT1000D I measured had horrid IMD measurements at ten watts, as did an IC751A.

My worry is that the series of articles stemming from incorrect design parameters (with values mainly selected to make the tube look appealing) will result in some nasty signals on the air. The "standard" 50 grid resistor *seems* like a case of "stick this part there" engineering.

>While I now have a spare pair of 8875s for my MLA-2500, I think I blew
>one of my "good" tubes in the old HF mailforwarding days (haven't had
>a chance to work with it since moving) so I'm looking at the 4CX800A
>retrofit as a bit of future protection.

>W6TC was marketing manager for Eimac for many years before retiring in
>approximately 1990. He joined Svetlana, USA shortly after that as VP of
>marketing.

It would be nice to see some tetrode articles explaining proper design, rather than written exclusively as marketing tools. But then salesmen aren't always good engineers, or vice versa.

>:>Doesn't QST watch for that?
>

>I would have expected the editors at QST to have pulled the last two
>paragraphs of George's article. In my opinion, they were not called
>for, supported by the facts, or justified in what was, otherwise,
>generally an interesting history of the high power vacuum tube in
>amateur radio.

The facts support your opinion Joe. It was a shame a well written article became a marketing tool, and especially shameful incorrect information unrelated to the subject crept in. I found the thinly veiled and false denigration of Eimac zero bias triodes tasteless. There is no reason for that type of nasty and untruthful marketing.

Anyway, what was the grid bias of the tube and class of operation? Did the author include a screen meter? Was there an energy storage component at the screen to improve dynamic regulation during voice peaks?

Tetrode circuits are a real design pain compared to triodes, and I've never seen any of the "marketing tools" the author has gotten published properly address tetrode design. Of course that may be because I have "an Ox that was gored, or a tempest in a tea pot, or a bad hair day".

Or it could be because IMD related splatter from poor designs annoys me.

73,
Tom

I can tell you a **poor source** for TVI filters, Tucker electronics.

The Tucker low-pass filter my friend bought was in a pretty looking, heavy case. But the case had paint on the cover mounting edges and insulating washers under the cover screws. It had long wire lead conventional disk capacitors and toroids as the filter element. The construction was unthinkably POOR for a VHF-UHF filter.

It had severe case radiation, and poor VHF-UHF attenuation. It actually CAUSED TVI in my friend's installation!

We replaced it with a jumper and TVI was reduced, we added an old Bencher and the TVI went away!

Probably because we don't agree with you that the article was in
fact a horribly technically inaccurate advertising ploy. It was
a nice historical overview of amplifier tubes used in amateur
and commercial designs over several decades. Very little hard
technical data one way or the other was presented to be upset
about.

It sounds like you are after something other than RACES, or you have
gotten some bad data. If you read Part 97.407, you'll see that RACES
operation takes place INSIDE the amateur bands, specifically 144.50
-144.71 and 146-148 MHz. There are NO frequencies authorized by the FCC
for RACES use in the area of 153 MHz.

I just bought one at a hamfest less than a month ago. I had to buy manuals for mine straight from yaesu. The owner's manual is $7.31 and the service manual is $15.69. Shipping was 4.00 for a grand total of $27.00. Their number is 310-404-2700.
Also, their's a little black switch behind the dial when you take the case off. Flip this and it opens up the transmitter for all freqs. Mine was turned on when I bought it.

I have the owner's manual AND the service manual for the
TR-7600 (along with the radio and the RM-76 controller,
and the RM-76 service manual). E-mail me your address,
and I'll copy what you need and send it to you (but it
will be about three weeks, if you can wait that long).

Sorry if this has been covered before, but I am hearing alot lately about linking repeater systems via the internet. Anyone have any information about required software and hardware interfacing, and what server on the internet needs to be accessed.

Thanks in advance for any help. Please reply directly via e-mail since I don't subscribe to all the lists.

>------------------------------

The TS-870S did not seem to have the nice features of the Yaesu radio. Just looking at its schematics, it appears that it has the same Mars/Cap alteration as did the 850 and 450. The only difference is that there is no diodes to cut but only resistors. I did not find any others menus besides the calibration menu (N.R.+SSB on power on). There is another menu ?? (N.R.+CW on power on) just shows the word READY and 3 possibles positions but no further indication, besides an error code for the DSP. ANY Suggestions ???

From PY1 BY
(cesar).

As I have no get this in any Ham-digest I hace received I'm sending it again

1336. TS-870 review

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-23 00:00:00 UTC
From: cesar@iq.ufrj.BR
Message-ID: <199604231742.RAA12729@server.iq.ufrj.br>
Source record: 202234

I have just take a look on the Peter Hart review on RADCOMM (RSGB) about the TS870.
I find his results very interesting as I've just bought one.
My main use for it is in the 40 and 80Meters and despite the measurements (that I do not have any questions about its accuracy), up to now I have not found any problems relating to blocking in SSB.
Yesterday night I was in 7.194MHz just between two broadcasting stations (~20 dB over nine) listening to two US stations (S3-5) and I did not find any problem. However when I changed to CW I did find that the noise level did increase and splatters did occur in the nearby frequency.
A quickly analysis between the schematics of the 850 and the 870 showed that the two radios have in general the same set of IF filters. So that brings me to my questions:
Assuming they have not change the mixing levels, what have changed among the two radios? Note that I have no questions about the DSP in the end of the chain.
Does any one could explain how the CW signal paths that seem to be routed through the same set of filters as in the case of SSB do show some degradation that I could not detect in SSB?
Further if the 3KHz (8.8MHz) filter is supposed to cut 70dB at 5KHz how could I have an interference 10KHz AWAY as I have found in CW?

Anyway I hope KENWOOD will address the subject very soon because as the reviewers have mentioned the 870 has one of the best audio (in Amateur radio) I have listened in the past 20 years.

Source record: 202238

I was wondering if any out here can answer some questions about the Yaesu FT-50R?

How is it on intermod?

I made the mistake once of buying a Kenwood TH-79a. That thing was useless as it would pick up every radiating if oscillator with in a block of itself. Was always hearing garbage, images etc. It went back to kenwood and was told thats the way it is and learn to live with it. Question...is the FT-50 prone to suck up this crud too?

How do you like the rx audio, qualitity?, loudness?

Battery life?

Anyone hack any mods?

Thanks !

Yaesu told me on the phone today that the FTT-12 keypad option will not be available till sometime in May.

1345. Looking for mods for 2/2

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-23 00:00:00 UTC
From: Clint.Bradford@bbs.woodybbs.com
Message-ID: <580_9604232234@woodybbs.com>
Source record: 202243

(Continued from previous message)

Enhancement of Microphone Frequency Response

1) To increase average depth of modulation
-- -- -------------- ----- -- ----------
Remove top cover of the radio and with the display facing you and the radio upright locate IC3 (MJM45585) near the bottom right hand corner of the main large board.

Just to the right of this IC locate c75 (56 pf) and remove it. This will increase the gain of the microphone Preamp considerably but without overmodulation. If you find the compression excessive(i.e. background noise) open the microphone and insert a 470 ohm resistor between the hot side of the mic insert and the input (white lead).

This will reduce the gain somewhat but will still give you much increased "talk power" (percy's words, not mine. Adam).

2) To increase audio response in the high mids
-- -- -------- ----- -------- -- --- ---- ----

This simple mod will recrease the audio response in TX in the 2 to 2.7 khz region giving higher articulation and move intelligibility under weak signal conditions.

Locate IC3 as before on the large main board and the radio positioned as before

Locate a 5.6k and a 4.7k resistor just below IC3.
Solder a 0.015 mf (16v) capacitor between the left side of the 4.7k to the right side of the 5.6k resistor.

These two mods work together to give improved readability on SSB under DX conditions.

------ -- ---

Percy, KF2AT, for taking the chance on his own radio, and wildly succeeding.
Jeff, N2LJA, for selling the radio to Percy and writing it off as a loss.
Tony, Kb2JYN, for being the test rabbit. May the rabbit rest in peace.

Fair Warning and Friendly Advice To Very Anxious and Excited People

---- ------- --- -------- ------ -- ---- ------- --- ------- ------
We are not responsible for any damage on your part. If you don't know
don't do it. Let someone with more experience do it.

Thank you for your interest. The Tandy HTX-100 Amateur Radio Transceiver is
a close cousin of the Uniden HR-2510 (Listed as the Amateur Radio Mode
HR- 2510 (UT-550B). HTX for Ham Tranceiver, HR for Ham Radio, UT for Uniden
Transceiver. We can assume the A suffix for the HTX-100.)

My first HF radio as a Novice was a HTX-100, so there was always a lingering
question as if the Tandy model was capable of similar capabilities. I had
spent many hours examining the mini-schematic diagram at the end of the manual.

This information was derived from the buying of a HR-2510 service manual
at the local hamfest. When I examined the PLL schematic, I realized that
I was looking at a prior generation of the same PLL circuit. It helped
to complete the purchase.

The Uniden HR-2510 microcontroller u1201 is a 46 pin Dual Inline Package.
On the diagnostic voltage table for the microcontroller, there are two pins
labeled (34)AMATEUR and (35)GND aside of each other. They are pulled to GROUND.

#34 will open TX/RX from 26.000 Mhz to 28.000 Mhz, #35 will open 29.7 to 30 Mhz

On the schematic for the HTX-100, there are similar pins 28 and 29 on U1208
pulled up by a resistor pack to Vcc.

The Tandy model microcontroller is a surface-mount device and the pins on the chips don't bend: they SNAP. The steel used on the pins are quite different. Do not attempt to physically pull on the pins of the package.

Percy KF2AT wrote the mods for the HTX-100.
Use common sense, a grounded soldering iron, and enjoy the mods.

Adam Kb2Jpd

*Extended Frequency Coverage from 26.000 Mhz to 30.000 Mhz

_____ _____ _____ ____ _____ ___ __ _____ ___

Thanks Percy for being the first one.

Remove bottom cover. With the radio upside down and display facing you remove the synthesizer board with the four screws, this is near the front of the radio

This gives access to the small board underneath with the surface mount components on it. Locate the processor chip IC401 (UC-1208).Locate pins 28 and 29 which are on the right hand side of the chip and are 4th and 5th from the top. Note they are bridged with solder.

CAREFULLY cut the copper track NEXT to the pins. DO NOT attempt to unsolder the two pins form the board. Use a GROUNDED soldering iron. Locate the two rows of connector pins above the chip.

On the bottom row locate the last pin on the right. Verify with a VOM that this pin has + five volts. Solder a 10k (1/4 w) resistor between this pin and pins 28 and 29 on IC401.The synthesizer will now tune from 26.00 Mhz to 30 Mhz.

---

*Simple RF Wattage Enhancement to 35 Watts

With the radio in the same position as before, locate VR5 in the top left hand corner. This is the RF high power preset.

Lift and bend the wiper so that is is permanently disconnected form the track. Solder a 47k resistor (1/4 watt) between the wiper and the left hand side of the track.

This should increase the RF power output to around 35 watts but you will now not be able to trim the power output. The Low power trim will function as before.

In my experience (I worked for a high-end audio manufacturer for many years, and both solid state and tube equipment was produced), there are two primary EXPLAINABLE (some of this stuff is almost unquantifiable) reasons why tubes sound "better" than transistors.

The most obvious reason is that the overload characteristics and clipping are much "smoother", but I think the MAIN difference (which relates to this smoothness) is the spectral content of the distortions involved.

Due to their physical nature and construction, tubes produce predominantly EVEN harmonic content in the distortions they generate. Even harmonics are pleasing to the ear and sound "smoother".

Bipolar transistors on the other hand, produce predominantly ODD harmonics, which are atonal to the ear, and are interpreted as "harsh" by most people. So even when a circuit isn't in overload, the difference between tube and transistor is apparent.

Put these circuits side by side on an audio spectrum analyzer and you can see these spectral content differences.

>
>Hello friends:
>
>Anybody out there who runs the STANDARD baby C 508 A. Does this radio
>has a 1750 Hz tone burst for opening repeaters in good old Europe?

Yes, while holding the PTT button down, press the CALL button and a 1750
Hz tone will be sent for as long as you hold CALL down. (The tone is
not heard in the speaker). This feature is not mentioned in the manual
but appears to work the same on other Standard HT's as well (I also have
a 168 and a 178). I suspect the revised model rumored to be on the
shelves now continues to support the 1750 Hz tone, though it may not
mention it in the US version of the manual.

>How do you like this puppy?
>I read that it has a very low power consumtion, is this true?
>E. g. you can monitor a frequency with a power safe option around 3 weeks ...
>
I haven't tried that but it seems plausible. I use 850 maH NiCd batteries
and recharge them each night, it will scan and receive (power saver not
active) for much longer than all day on a full charge (maybe 20 hours).
Results with alkaline batteries would be 3 or 4 times longer at least.
The transmitter is easy on the batteries too, as I remember the spec was
300 mA while transmitting. Even if not essential for saving battery
power, it would be nice if it offered an "Extra Low" power mode because
there actually are situations where 280 mW is too much power.

Source record: 202403

I am rebuilding an old Alpha 77 linear amplifier that was build by ETO in Florida in approx 1972. It is serial number 2006. It is one 8877 tube model. Key production points are the use of point to point wiring of the grid over-current relay and input antenna change-over relay in the bottom of the PA compartment. Later production models in the 70's used a sigle circuit board in the bottom of the PA compartment that had the above relays mounted on it along with the cathode zener diode.

I will pay for reproduction and mailing costs for a copy plus your time!

>complete signal/picture loss.

Hi Joe,

I know what you probably meant by this, but not all readers will. When signal integrity is lost, the video "freezes" until the data stream is recaptured. During this interval, audio is muted.

Incidentally, I had a chance to witness a live HDTV broadcast on 2.5 GHz a few years ago at a Wireless Cable convention. The carrier to noise ratio of the received signal was terrible, but picture quality was truly superb. This despite the fact that a single 6 MHz cahnnel was being used to carry four separate programs!

:>
:>I have not seen the article Joe. Do they regulate thee screen and grid
:>bias? How do they drive the tubes, cathode or grid? Do they monitor the
:>screen current and protect it?
:>

Tom, the screen and grid are both regulated supplies. The screen at about 350 volts with voltage foldback as the current increases (to prevent the screen from dissipating excess power). The grid is also regulated (zener diode).

The tube is grid drive with an untuned resistive termination (50 Ohms with a slight inductance by using a mix of non-inductive and wire wound resistors).

While I now have a spare pair of 8875s for my MLA-2500, I think I blew one of my "good" tubes in the old HF mailforwarding days (haven't had a chance to work with it since moving) so I'm looking at the 4CX800A retrofit as a bit of future protection.

:>By the way, thank you for the direct reply to my question. I suspected
:>there was a bit of "marketing" involved in the article.

W6TC was marketing manager for Eimac for many years before retiring in approximately 1990. He joined Svetlana, USA shortly after that as VP of marketing. I just saw him again last week at the NAB convention in Las Vegas. Svetlana are introducing some interesting products for the broadcast field (including a multi-beam Inductive Output Tube class device for UHF TV (HDTV) service).

:>Doesn't QST watch for that?

I would have expected the editors at QST to have pulled the last two paragraphs of George's article. In my opinion, they were not called for, supported by the facts, or justified in what was, otherwise, generally an interesting history of the high power vacuum tube in amateur radio.

1359. What does the HTX-202 "S meter" actually indicate?

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-23 00:00:00 UTC
From: teacherjh@aol.com
Message-ID: <4li66m$935@newsbf02.news.aol.com>
Source record: 202411

When one transmits on the RS HTX-202, a meter "lights up" indicating (presumably) the transmit power... At low power, it indicates (usually) 3 or so, at high (battery) power it usually hovers around five to seven, and at full (car battery) high power, it indicates 9+.

However, it varies depending on position, antenna, whim, etc. What is it =actually= indicating on transmit, and in what units? Forward power? Reverse power? SWR? Battery temperature?

Same question on recieve.

Thanks for any information in advance. :)

Mike:
I own an IC-2000H and am very pleased with it. If you want to wire it
up for packet, you will have to get your hands on an RJ-45 connector. I
found that I could use a good quality network patch cable (10Base-T) available
for about $10 from just about and computer store or catalog. This gives you
a 10' cable with two ends on it. Cut it in half, and you have 2 5' cables
that you can cobble up any way you need. I use one for an extension in my
car when I work special events. I also know of at least one person using
the 2000 for packet at 1200baud, so I know it works. Good luck, and have fun.

>viewed in the frequency domain, if it is *not* the creation of
>odd-order overtones?

I'm not sure I have a full explanation, but the clipped waveform at
the output of a tube-type audio amplifier is noticeably more rounded.
The leading and trailing edges are also not nearly as sharp-cornered.
By comparison, the clipped output of a solid-state amplifier looks
like a near-perfect square wave.

As pointed out by someone else, this is in addition to the fact that
harmonic distortion within the tube audio amplifier (when it is
operated below clipping) contains fewer odd-order products.

Deep dark secret!

MOTOROLA RADIUS GP-300 SERIES

1. READ a 16 channel Radius GP-300 into the program/memory
(requires standard black box and rib).

2. Remove the 16 channel radio and install the Target 4 channel Radius
onto the rib).

3. WRITE the 16 channel data into the 4 channel memory!

4. Reprogram your 16 new (if desired) channels into the GP-300.

6. Move the Channel Selector knob to clear the 4 channel mechanical
stop.

6. Order new 16 channel plate and enjoy!

I've done this mod to 4 UHF GP-300's with 100% success! I have NOT
tried this method with a VHF GP-300. DON'T expect to move a VHF
Radius to UHF, or UHF to VHF. That is out of the question.

The Raymond Sarrio Company's Ham Radio WWW site is proud to announce a FREE Ham Radio classified advertising page at http://www.csz.com/sarrio.html.

This new classified section will allow Hams to search for equipement with the help of a search engine--no need to scroll through 100's of listing before you find that special piece of gear. Plus, when you find the gear your interested in, each listing comes with point-and-click e-mail access, direct to the Ham that listed the item.

For those Hams with gear to sell, take note! It is absolutely FREE to list your equipment within Ham Classifieds, and there will be no posting time delays. Your posting will go on-line, in our classified search engine, immediately. All you need do is fill out a simple forms page, and upon its (point-and-click) submission, your "For Sale" advertisement is on-line within 1 hour. I will be purging the classified listing initially about once every month, but that timeline will shorten as our classified numbers go up. Give it a try, and let me know how you like it. 73's Ray

1379. Motorola HT90 UHF Conversion - Practical???

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-24 00:00:00 UTC
From: rossanalytical@cybergate.net
Message-ID: <4lmgqc$kd2@galaxy.cybergate.net>
Source record: 202181

I bought a Motorola HT90 Handheld UHF radio and charger at a hamfest recently. I obtained the service manual for it with schematics, crystal freq. equations, and tuning procedures.

It will require equiptment that I do not currently own to perform the tuning as described in the manual. Is there any place that will recrystal and tune this radio down to an amateur freqency for a reasonable cost?

Thanks

I've used both the FT-736 and TS-790. I own the latter. Ergonomically
it can be a bit difficult to get used to, but it's a good rig. The
FT-736 is very goo, too, and perhaps easier to learn to use. Trouble is,
it's more expensive.

:>
:>tdengler@ix.netcom.com

The only thing *I* can tell you about them is that they are RX converters to be used with older (tube type) Hf rigs. They were designed to work with the HF rig set on 14 Mhz (20M).The CB-6 (I actually have one of these, but I've never used it. I have an HA-6 transverter) uses a 36 Mhz crystal in the socket. The tubes are (I believe) 6 volt filaments, but I don't know what the plate voltage is supposed to be.

Maybe someone else could give both of us some further information.

Good luck.

I've owned a 2000H for about three months now and so far,...so good.
I haven't bothered to use it on packet as:

1) I already have a rig (AZDEN PCS-4000) on packet.

2) Its got that funky RJ-11 style mic connector that I'm not gonna
mess with.

Seems to be a pretty good rig on voice with fair intermod rejection.
Like any of the new rigs with a gazillion features and half a dozen
buttons, everytime you want to program in a new freq, tone, offset,
etc., its time to pull out the manual. Certainly not the thing to try
while mobile in motion! I've got three 2 Meter rigs and one
dualbander and none of them work the same way. Have fun Mike!

Opinions expressed herein are my own and may not represent those of my employer.

1393. 400Mhz Oscillator + Mixer. Help?

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-24 00:00:00 UTC
From: mat@shallot.demon.co.uk
Message-ID: <4llaim$1eh@shallot.demon.co.uk>
Source record: 202256

Ok, this is homemade stuff...

I have a signal at about 144Mhz (very low power) and want to mix this with 300 odd Mhz to put it in the 400Mhz band.

300 Mhz Local Oscillator (running off a 9.1v zenor) is an LC type circuit. If you have G.R.Jessop's VHF-UHF manual it's on page 4.17. I know the oscillator is running, I can pick it up on a reciever.

This then mixes with the input signal using a "simple diode mixer" (page 4.24 top left) Basically this is 2 capacitors (100pf) joing the 2 signals into a diode.

The problem is simple. It doesn't work! :)

It this type of mixer a good idea? (I don't want to get into cavitys and complicated stuff) But perhaps something FET/Transistor based??

What kind of screening do I need between the oscillator and the mixer? presumably lots?

I do not know an awfull lot about rf electronics (I am building this for a friend)

If you can suggest any improvements in the circuit or point me towards a better circuit or book then I would be most gratefull.

Thanks,
Mat

> can provide will be greatly appreciated.

There are a number of reasons for a separate ground. Someone will no doubt fill you in with more than this, but here are a couple:

First, you need as low an impedance to earth as possible and as short a path as possible for the antenna. The ground with your mains supply could have quite a highish impedance to earth, and the wire distance between your set and earth could be quite long. So it's worth putting your own good ground in.

Second, using the mains earth as your RF ground means that you risk injecting RF into the mains. This could (will?) cause TVI. You can put a filter in (for example, several turns of the earth wire round a suitable ferrite toroid) between the set and the mains earth, but then you don't have an RF ground any more for the antenna.

It's worth having a look at the section on grounds in a number of books. I like the section in the RSGB's Handbook, but I am sure there are others.

What I have is a separate RF ground of four 1.5 metre copper pipes connected together and to the set by a thick (10 sq millimetres) insulated copper wire. Where the RF ground enters the house, it's connected as well to the mains earth via about 5 turns each on four ferrite toroids. This link prevents RF injection into the mains, but makes sure that my set is grounded to the mains earth. There is no direct connection between the rig and the mains earth apart from this.

>so if I am to read this newsgroup. Why can't you and your kind simply
>follow the newsgroup guidelines????

First of all, if you pay $10 for each for sale posting, you need to get another internet provider because you are getting ripped off.. As for your comment about "you and your kind", I don't post for sale items on this newsgroup. I was just simply stating that some people don't have access to ALL the usenet newgroups. If you are paying $10 a post I sure hope you are getting ALL of the usenet groups!! I don't understand why people like you want to flame people for simple making a comment?! My original message was not intended to be "flame bait." Most people don't have a clue about how newgroups are distributed throughout the internet and this is definately not the place to discuss it.

1397. Re: FT-900 vs IC706 which is better?

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-24 00:00:00 UTC
From: "Gregory J. Buhyoff" <buhyoff@vt.edu>
Message-ID: <4lllv1$3dp@solaris.cc.vt.edu>
Source record: 202260

I have owned an IC 706 and own a FT 900. They were compared side by side. The FT 900 wins hands down. It has a very good receiver and does not suffer from IMD and overload like the 706 does. In addition the IC 706 CW filters are the worst I have ever experienced in a radio of that price range. The blowby is terrible. The menu system is good but awkward to use unless your use of the radio is casual at best. The ergonomics of the FT 900 are very good. You have a full range of connectors and ports on the FT 900 which you do not on the 706 due to its size. The 706 is a fun radio but I would not choose it for anything other than very casual operation on HF. Finally, I found its six meter recieve to lack sensitivity and this was problematic enough for me to determine that it would not be good for dx'ing on six. The 706 is fun radio and would be great for portable or causual operating -- that is my bottom line.

>
> Alan

There isn't any harm in adding additional grounding electrodes or systems. The harmful situation is having independent grounds connected to different points in the house. What you want to avoid are ground loops through the house wiring.

Ideally, all wiring should enter and leave the house at one point, and all outside grounds should connect at that same point. What this does is prevent ground loops and improve the ground connection.

This section of the FAQ is worded so as to be misleading at best.
Article 250 of the NEC is the controlling text in the US. It requires
that all Earthed electrodes be tied together, that includes any made
electrodes (ground rods), any metallic water piping systems, any structural
steel, any Ufer grounds (rebar in concrete), etc, and defines that
interconnected system as a single grounding system.

Article 250 only requires a single point connection for *neutral*, however,
and not for Earthed electrodes in general. The single point for neutral must
be in the distribution box. Other Earth connections can be interconnected via
the 3rd wire safety (green) conductor in the electrical wiring, by metallic
raceways, by bonding straps installed in convienent locations, etc. In fact

it is impossible to single point structural steel Earth connections since each vertical support represents a separate connection to Earth, but all of them are bonded together by the horizontal members in a complex lattice rather than a star.

250-21 allows exceptions to prevent objectionable currents on the grounding system. The toroid mentioned above is a permissable method of preventing objectionable RF currents from flowing over parts of the grounding system.

Now despite the NEC's permission to install a system this way, I would strongly encourage a single point be established for the ham station so as to short circuit any circulating ground system currents that may use any of the station equipment as a common path. This is what a ground window does, and I've expounded on that topic frequently here.

This does *not* mean, however, that all Earthed electrodes for the entire house have to be brought together at only one single point. That may be desirable in some cases, but it isn't required, and can be *undesirable* or impossible under some circumstances. Usually, a number of single points (ground windows) should be established near groups of equipment used together. And these single points can then be tied together in any convienent manner to form the total grounding system.

1403. Saturn 6 tuning - HELP!!

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-25 00:00:00 UTC
From: darryl.linkow@grinder.com
Message-ID: <8BF5277.01A6001661.uuout@grinder.com>
Source record: 202066

Hello all and thanks for reading this. I just acquired an old Saturn 6 antenna and am having a difficult time getting the SWR down below 2.5 to 1. I am using the MFJ-259 analyzer. I am just curious if perhaps part of the antenna is missing? There are two screws attached to a piece of phenolic board. I have attached the shield and center conductor of some RG-58 coax to these screws as the feedpoint. I am just curious if perhaps there is a tuning device (other than the capacitor plate adjustment) or a balun that should be connected to these screws on the phenolic board that might be missing? Also, might anyone have an instruction sheet or manual that came with the antenna that I might get a copy of? Any help would be appreciated.

I am looking for a dead FNB31 battery for a Yease FT-51R. I am willing to pay for the shipping and give the person a few dollars for the trouble of packing it up. I want to use it as a dummy battery in the PA10 Mobile Charger, it will just be conducting the 12V DC for me.

Also if anyone has any info on a "Ear Mike" I would be very inerested in hearing about them. I need one for noisy conditions (convertable car).

Drop me an email and we can work out the details.

Hi,
I have a TS-830S and am currently using a RS mobile mic on it.
It seems to work good. I have the mic gain and compression settings on
the rig.
What advantages are there to using a base type microphone with an amplifier
in it? Do I really need one? Will it improve my transmissions?

Thanks for your reply

Gary Ross Hoffman <gary@carcs3> wrote:
>Can someone explain the difference between "intermod" and
>"front end overload"?
>Thanks

I'm surprised that no one has followed up on this simple yet
pointed question. Many hams talk about intermod yet I suspect
that few know what the term really means.
Maybe its in the wrong newsgroup. *rec.radio.amateur.misc*
seems to mostly contain followups to Burt, code debates, FM-25
testimonials, and attacks/defense of ham radio in general.
I will crosspost this to *rec.radio.amateur.equipment* and
route followups to that group which is closest to the technical
segment of ham radio, apparently a declining vestage.

Its been said that the best way to extract correct information
from the Net is to first post incorrect information, so here
goes:

Front End Overload occurs when a nearby strong signal drives one
or more of the active devices in the initial RF circuits of a
receiver into their non-linear regions. This may create
additional products due to the mixing action of the non-linear
device. The result may be spurious signals all over the band.
In other cases it may cause the receiver to become deaf to weak
signals because the active device has been shifted out of the
weak signal region.

Intermod, or Intermodulation occurs when a strong signal that
is not within the receiver's passband is amplified by
successive stages anyway until it is strong enough to overload
an active device and drive it into a non-linear condition. In
this non-linear condition the device will mix signals with other
weaker signals as well as the intended signal. Many more signals
will be created by the sum and difference of the mixing action.
Some of these product signals may fall within the Intermediate
frequency passband and be further amplified by the receiver.
This is similar to front end overload except that the offending
signal was not strong enough or close enough to cause initial front
end overload. It was instead amplified within the receiver's
early stages until it did eventually cause an overload condition
in a downstream stage.

Both of these problems can be cured with tighter filter circuits
on the front end of the receiver, preferably before any active
devices. Cavity filters work good for VHF/UHF but are expensive
and too narrow sometimes. Another cure is reducing the RF gain.
If the spurious signals suddenly go away while turning down the
RF gain, suspect that intermod was occuring within the RF stages.
Vacuum tubes are not as susceptable to either of these problems,
I don't how susceptible the various flavors of FET's are compared
to bipolar transistors.

A related subject not curable with any of these methods is the external
mixing at dissimilar metalic joints which may create mixing products
outside of the receiver. A local rusty rain gutter for instance.

Let's not followup to this with statements like 'go read some ARRL
book". Please.

From: joep@jersey.net
Message-ID: <4loo1o$us@hermes.jersey.net>
Source record: 202076

If this is not the correct newsgroup for this question, please suggest another.

I have an Icom IC-28H which I would like to install in my '93 Nissan Stanza.

1) Will the RF cause any problem with the car's computer chip? It looks like the chip is installed just to the left of the drivers left foot in the chasis wall. (my guess)

2) Does any one know how to get power to the transceiver. I checked almost every inch inside the car and could not find wires of heavy enough guage to use. I tried fishing a cable thru the firewall (to connect directly to the battery terminals), but gave up after about 2 hours search looking for a hole I could use.

I successfully installed the ICOM in my previous car which was a '87 Honda Accord.

Any help or suggestions would be appreciated.

Thanks,
Joe, NU2H

From: Bill Crocker <billc@mail.rust.net>
Message-ID: <317FDD5D.1DCF@mail.rust.net>
Source record: 202078

Chip:

Overall, the FT-50 seems pretty nice. I did find the display a little hard to read (my eyes aren't as good as they used to be), but that's expected on something that small. The wide-band receive is nice and works well, however, they advertise WFM (Wide FM), and it's not! There has been conflicting rumors about an engineering design flaw where they used a 25 KHz filter, when it should have been a 75 KHz one. Another Internet member claimed that a Yeasu engineer told him that. My local radio shop called Yeasu to confirm, and they were told it was not an error, but that there wasn't enough room for a 75 KHz filter. If that's the case, then they need to re-write their advertising.

The audio packs a solid punch for a HT this small, and it doesn't distort unless it's wide open.

I did return mine however.

Source record: 202079

I have had an Ameco 2 meter unit for years - paid $5 for it at a hamfest as I recall. I re-tubed mine with a 6DJ8 high transconductance instrumentation twin triode and a 6EA8 for the local oscillator/mixer. I believe originally Ameco used a 6BK7 and 6U8. The mixer output is un-tuned. It is simply a 4.7K ohm plate resistor and .001uf dc blocking capacitor to couple the output, so running the output to a general coverage receiver with a preselector or antenna trimmer, allows you to tune thru quite a bit of the VHF spectrum. I use a 25.6 Mhz crystal oscillating on the 5th overtone - 128 mhz. That puts 144 Mhz at 16 Mhz and 155 Mhz at 27 Mhz. You can listen to the 2 meter band or the Public Service band or tune down to the aircraft band. I use a 180 volt plate supply - as I recall it requires about 10 ma.

Happy listening!

Steve Kennedy (prografx@teleport.com) wrote:

: In my experience (I worked for a high-end audio manufacturer for many
: years, and both solid state and tube equipment was produced), there
: are two primary EXPLAINABLE (some of this stuff is almost
: unquantifiable) reasons why tubes sound "better" than transistors.
:
: The most obvious reason is that the overload characteristics and
: clipping are much "smoother", but I think the MAIN difference (which
: relates to this smoothness) is the spectral content of the distortions
: involved.
:
: Due to their physical nature and construction, tubes produce
: predominantly EVEN harmonic content in the distortions they generate.
: Even harmonics are pleasing to the ear and sound "smoother".

I find this hard to believe. Clipping, in the time domain, can be described by a series of odd-order harmonics. The even order values cancel out. This is independent of whether the clipping occurs in a transistor or tube amp.

I suspect the main difference is due to tube amps having an output transformer. The hysteresis/inductance would "round" any impulse waveforms. In practice, this means that the transformer would be distorting the clipped waveform even further - but the resulting sound would not be as "harsh".

Bill

The old rock-bound Motorola mobile radios form the basis for a _lot_ of
the Ham repeaters around, too. They are very good radios, especially
considering the prices on the surplus market, and repeaters rarely need
to be "frequency agile".

Hi Mike,

I have two Yaesu FT-2400's and one IC-2000. The 2000 has a few more features than the 2400. As far a performance goes, both are very good radios. The IC-2000 was designed to go after the FT-2400/2500 market. I'd say that Icom did good with their radio, its a solid performer. I get good unsolicited audio comments.

1425. Re: HTX202 low audio with speaker/mic

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-25 00:00:00 UTC
From: Jeff Goebel <jgoebel@rrnet.com>
Message-ID: <317F74A0.7797@rrnet.com>
Source record: 202088

Bob,

I found this a few months ago when I first bought my HTX-202. I haven't tryed it yet though.

Good luck,

Jeff N0VHB
jgoebel@rrnet.com

http://pages.prodigy.com/CA/LA/htx202htx404/htx202htx404.html

Title : Low ext mic audio on the HTX-202 and
HTX-404

If you own the HTX radio you probably already know about the low external audio problem. I have tried a few
different brand mic's and they all failed to get any significant audio into the radio. There is a good reason for this. The
problem is the radio does not provide enough voltage to properly bias an ext condenser mic. When the radio is keyed
the voltage at the ext condenser mic drops to about 2 tenths of a volt. Most common condenser mic's need a minimum
of 2 volts and a nominal of about 4.5 volts. Design flaw or design feature. You be the judge. There is an easy way to get
around this. I will tell you how to modify the Radio Shack speaker mic to get very respectable audio out of it. You then
will be able to amaze all the smug Yaesu and Icom owners that have looked down at your HTX rig.

You will need the following parts from your friendly neighborhood Radio Shack

cat num,.....description,.....generic

19-310.....speaker mic

270-430.....lithium batt holder....20 mm single cell

23-162.....lithium battery.....dl2032..3v 180mah

270-092.....condenser mic.....-65 db sens
.....2v min 10v max

.33 microfarad cap,disc type or any small profile type cap

At this point I should say that this is a " use at your own risk" modification. It is not approved by the manufacturer and if
they knew it would probably void your warranty. Any damage to your radio because of an incorrectly implemented

mod to the speaker mike is solely your responsibility. Now having said that, probably the only thing to happen if you
blow the mic mod is that the mic won't work or you won't be able to key the radio from the external ptt switch. They
made the radio hard to hurt through the ext mike jack.

#1:unsolder the ptt switch. #2:cut the leads to the mic element and remove original mic. #3:connect the red wire from
the main cable that was going to the ptt switch before to the side of the resistor that is not connected to the speaker.
#4:install the ptt switch in line between the resistor and ground which is the minus terminal on the speaker. #5:connect
the .33 mf cap to the top of the resistor where the red wire is. #6:connect the white signal wire from the condenser mic
to the other side of the .33mf cap. #7:connect the shield wire from the condenser mic to the ground side of the resistor.
This would be above the switch but on the low side of the resistor. This is important because if this is wrong the battery
will only last a few days instead of a year or more. #8:connect the minus side of the battery holder to the ground point
that is the minus terminal on the speaker. #9:connect the positive terminal of the battery holder to the red bias wire that
comes from the mic element. #10:install the battery. #11:check with a volt meter to check that the bias wire on the mic
is getting aprox 3.1 volts positve.

That should be it. The .33mf cap keeps the radio {red wire from main cable} from seeing the ext dc from the battery.
The ptt switch grounds the resistor and causes the radio to key and completes the ground for the mic element. When the
radio is not keyed the battery is looking at a high impeadance instead of the 3k impeadance the mic presents when in
circuit. I checked modulation on my rig by putting the HTX on a dummy load at low power and listened with
headphones to a scanner. this is a good way to insure that all is well before you take to the bands. Also I should note
that this type of mod can be made to other brand mic's. Before I tried the Radio Shack model I modified a MFJ-284.
The same principals are involved but in the case of the MFJ there is more latitude in how you accomplish the mod. The
ptt switch is dpdt on the MFJ and only spdt on the Radio Shack. Having two sets of switch contacts allows you to use
one set to ground the resistor and the other set to apply the positve voltage to the mic element. Applying the positive
voltage rather than grounding the mic is probably prefered. If you use the Radio Shack mic you don't have much choice
and will need to use the grounding method on the mic.

Now there are better parts available to do this mod, a noise cancelling higher sensetivity mic for instance. If you are
interested in really having a high performance mic send a self addressed stamped

envelope and I will tell you how obtain
these better performance parts. Send the envelope to:

Terrapin Sales P.O. Box 12426 La Crescenta, Ca. 91224-5426

Another cool place for HTX-202 and HTX-404 info as well as other ham related topics is at the following address.

1427. Standard C550 C558 problem

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-25 00:00:00 UTC
From: Giuseppe Fabbri <gfabbri@www.iper.net>
Message-ID: <4lo3q5$emi@cnn.iper.net>
Source record: 202090

Hallo,

I'm looking for any owners of the Standard C550 (or C558) transceiver. I think I have burned the 70 cm RF power module (for the second time!) and I can't understand when and why. Is there anybody that had this problem or knows anything about it?

I always take care of it and I never had any problem with 2 meters band or with others transceivers that I've got. After the first repair (the assistance said the RF module had burned) the transceiver has the RF module M67749MR for 70 cm: before replacing it I'd like to know how to avoid this problem (limiting the power, improving the termal dissipation...) or if there is another module that works better.

Thanks for your help

Giuseppe - IK4ZHB

>In article <4lhoa6$7ck@ram2.ramlink.net>, subich@ramlink.net (Joe Subich)
>writes:
>
>>Tom, the screen and grid are both regulated supplies. The screen at
>>about 350 volts with voltage foldback as the current increases (to
>>prevent the screen from dissipating excess power). The grid is also
>>regulated (zener diode).
>>
>>The tube is grid drive with an untuned resistive termination (50 Ohms
>>with a slight inductance by using a mix of non-inductive and wire wound
>>resistors).

There's also a 20 ohm cathode resistor giving negative feedback to the
amplifier.

>What is the grid bias voltage of the tube and the class of the stage?

-56 volts, class AB1. Here are the parameters in full:

Plate voltage 2200
Screen voltage 350
Grid voltage -56
Zero-signal plate current 170 mA
Single-tone plate current 550 mA
Single-tone screen current 25 mA
Zero-signal plate diss 370 W
Drive power 60 W
Plate input power 1200 W
Plate output power 750 W
Efficiency 62.5%
Power gain 10.97 db

>I find it strange that all these tubes require a 50 ohm grid resistor to
>develop correct grid voltage swing with a 100 watt exciter. That almost
>seems too good to be true. I am trying to help three people get 4CX1600's

>solid state exciters get trashy when turned down that far. A FT1000D I
>measured had horrid IMD measurements at ten watts, as did an IC751A.

This amp requires 60 watts of drive. That's 54.77 volts across the
50 ohm grid resistor.

>My worry is that the series of articles stemming from incorrect design
>parameters (with values mainly selected to make the tube look appealing)
>will result in some nasty signals on the air. The "standard" 50 grid

>resistor *seems* like a case of "stick this part there" engineering.

Then perhaps you should look at the ARRL lab test data on the conversion (available on oak.oakland.edu). Second order products are down 50 db and third order products are down 68 db for single tone transmit on a frequency of 14.175 MHz at rated operating conditions. On the two tone test, worst case products are -38 db at 2 kHz from the carrier, and no more than -48 db at 4 kHz from the carrier. Not too shabby for a simple untuned input amp, and better than the MLA2500 did with the original pair of 8875 GG triodes.

>>I would have expected the editors at QST to have pulled the last two

:>was being used to carry four separate programs!
:>

What you observed was not HDTV in the present sense (a single 1050 line, progressive scan, 60 frame per second, 16:9 aspect ratio picture). Instead, you probably witnessed an example of HDTV's "scalability" - the ability to transmit several (the number varies between four and six depending on the "expert") normal NTSC resolution (the "new" term is Standard Definition Television or SDTV) signals in the digital domain.

The intriguing thing is that the "Grand Alliance" system slated for adoption by the FCC will operate with perfectly clean signals down to within .5 dB of the noise floor - the adaptive equalizers and precorrection are than good. UHF/VHF field tests in the Charlotte area last year showed the Grand Alliance system could withstand several hits (bad packets) per second and still provide adequate perceived signal quality. However, when the signal started to go, it went very quickly ... no ghosting, fading, etc. It was almost like turing out the light.

The biggest problem as far as TVI goes is lockup time (training time for the adaptive equalizers). If TVI causes a problem when the receiver is trying to acquire a signal, there are real problems.

I hope the broadcast industry will not fall victim to the low power myth that is being circulated in HDTV circles ("you'll only need about 30 KW to equal your current grabe B contours"). While 30 KW may provide a 1 dB margin at 55 miles (the line of sight horizon for most TV stations over flat ground), having extra fade margin at the horizon will increase program availability from 85% +/- to 99.5% and make reception much less susceptible to interference, etc.

The old grade B contours were based on the F(50,50) curves meaning that 50% of the receiver locations should receive service 50% of the time ... that works out to 25% of receivers actually getting a usable signal (that's not good enough for me!).

From: pwardell@sirinet.net
Message-ID: <4lmu05$j2i@ns2.sirinet.net>
Source record: 202194

Hello to all. Our club has recently come into the possesion of a new Radio Shack HTX-242 2 meter mobile radio. Our hopes are to use this radio as a remote base in conjunction with our DRC186 repeater controller. Side by side, the HTX-242 and the Kenwood TM-241A appear nearly identical. The Kenwood utilizes an 8 pin DIN type mike connector and the Radio Shack uses an 8 conductor modular plug (RJ-45). The pin-out for the HTX-242 is as follows:

1-Tone
2-Ground
3-Clock (CPU)
4-Control
5-Mic
6-PTT
7-5 VDC (500mA max)
8-Data (CPU)

Can anyone provide me with the pin-out for the Kenwood TM-241A radio. If anyone has already done the experimenting with this radio and a Doug Hall RBI-1 interface, please let me know how it went.

Thanks...Paul

>ferrite toroids. This link prevents RF injection into the mains, but
>makes sure that my set is grounded to the mains earth. There is no direct
>connection between the rig and the mains earth apart from this.

While this may be the thing to do in the U.K., I would recommend
against it. From the wiring faq (misc.consumers.house, sci.answers,
news.answers, and other places):

Furthermore, there should only be one grounding system in
a home. Some codes require more than one grounding electrode.
These will be connected together, or connected to the neutral
at a common point - still one grounding system. Adding additional
grounding electrodes connected to other portions of the house
wiring is unsafe and contrary to code.

Your connection connects extra grounding electrodes to the wiring
of the house. The FAQ is written for North America (U.S. and Canada),
but I would suspect that multiple ground (earth) connections is
inappropriate for good reason. Your connection through a toroid
is a fairly direct connection at power line frequency.

1443. ICOM AT-180 SSB problem

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-25 00:00:00 UTC
From: dgf@netcom.com
Message-ID: <dgfDqECFp.Mz9@netcom.com>
Source record: 202198

A month or so there was some discussion of problems some people were having with the ICOM AT-180 tuner not staying tuned when in SSB mode. I was easily able to replicate the problem (which is, the tuner light starts flashing and the tuner then goes offline when transmitting SSB, even tho the tuner could do a good match with CW/FM modes). Anyway, I sent the unit to ICOM requesting warranty service. The tech called me and said he was able to duplicate the problem (using a resistive mismatched load), and he fetched a brand new tuner and was able to replicate the problem on that too. Therefore, he decided that the tuner was not malfunctioning. So ICOM is sending the tuner back, complete with this problem. The service tech referred me to ICOM customer service, who I spoke to, and they agreed to refer the problem to ICOM Japan, but indicated that it would take a while to get a reply and how they would handle it in Japan was uncertain. The Customer Service rep, while very friendly/helpful, indicated that he had not heard of this problem before, and confirmed that he witnessed the bench test of my unit with the SSB-offline mode.

By the way, I tested a Yaesu FT900AT under many identical conditions and it never missed a beat. Same with the tuner in a Kenweird TS940SAT.

So if you are experiencing this kind of problem it would probably be worthwhile mentioning it to ICOM service in Bellvue, Washington. I don't know if ICOM will be able to address the problem or not, but the customer service rep sounded somewhat hopeful, and the service tech did understand the nature of the problem and was likewise helpful and friendly.

Hopefully ICOM JAPAN will come up with a service modification and those of us experiencing the problem will get updated. The customer service rep did assure me that ICOM would stand behind the product, so I'm not terribly worried right now.

Good luck,

73 Dave WB0GAZ dgf@netcom.com

Hello:

I'm looking for recommendations for a 70cm amp. With 2-3 watts
input, I'd like at least 20-30W output.

The amp will be used with a 9600bps data radio (The Tekk KS-900)
so I'd prefer something that has an outboard PTT connection, instead of
just having RF sensed switching.

So.... does anybody out there have a favorite amp that they would like
to recommend? :-)

Thanks,
- Rich

1450. WANTED: OLD K-40 MICROPHONE

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-25 00:00:00 UTC
From: Randy Padawer <padawer@usit.net>
Message-ID: <317F962D.2525@usit.net>
Source record: 202205
Cross-posted to: rec.radio.swap,rec.radio.shortwave,rec.radio.amateur.equipment,rec.radio.amateur.misc

I'm looking for one of the speech processor microphones offered by K-40 (American Antenna, Inc.) for so many years. If anyone has a working model in a junkbox somewhere, I'd very much appreciate an email. (I do realize this was a product marketed mostly toward the CB market, so please no flames <g>. I do have a use for the old pup.)

Thanks!

Randy Padawer, WA4FJF

As I recall, thinking back a few years: The EE model lacked some of the E's features, such as the RF processor, some of the 10m segments, and the 160m band. The earlier E's did have 11m capability (when the wire was clipped) and the FCC clamped down on Yaesu and required them to remove the 11m circuitry in later E models, allowing the addition of a user-set auxiliary band. Yaesu eventually called the non-11m version the FT-101F, one of which I still use.

FYI, addition of the WARC bands is straightforward. The old Fox-Tango club sold a conversion kit, but I was able to recreate most of the steps after they faded away. The 10.1 MHz band can be added instantly by jumpering a few wires from the bandswitch and sharing the 40m taps on the transmit tuned circuits. The trick is some tight soldering. 17 and 12m are set by installing the right crystals and re-tuning the oscillators. The manual gives instructions for calculating the crystal frequencies and I ordered them from JAN. I used the auxiliary band for 17 and removed the 10D (29.5-30.0 MHz) crystal to use that band for 12m.

>| Bob Boardman, Albuquerque, New Mexico - KC5SFW - ARRL, Upper Rio FM Society |
>| <boardman@cobra.unm.edu> PGP 2.6.2 public key available |

I had a problem with mine, and I took it back for repair.
It was tested and I was told it was "within specs" for
proper deviation. I got another unit after a complaint, and
the same thing. I got on the local repeater and someone
gave me the information to increase the deviation by turning
one of the pots inside (there were two if I remember). The
first time I turned the correct one (I forgot which) the
wrong way and had NO deviation, just carrier. Then I tried
it the other way and it was perfect. Find out which pot to
adjust and be careful taking it apart as it does not allow
separation of the front and back parts very far. If you
feel safer doing so, let someone else perform the mod for
you.

A side point, deviation is dependent on your voice, the
microphone, and the circuitry. Setting the deviation to,
say, 7 khz instead of 5 but talking softly will still give
you less than 5 khz deviation. If you go too far, you will
get complaints on poor audio quality. On mine, both with
the portable mic and the built-in mic, I got reports of low
modulation (deviation) until the mod was performed.

Sorry I can't help any more as to which pot to turn or which
way, but it's a start.

I've mounted a Kenwood TM-733A under the driver seat in my 1990 4Runner.
Used the remote kit and mounted the display on the steering column. I used a
Comet WS-1 window mount and a Diamond 770 dual band ant. on the rear left
passenger door. I can reach out the drivers windows to fold the ant. over
when entering garages.

The 4Runner is the V6 with EFI. The computer is mounted behind the front
passenger kick panel. I've run the VHF on 50 watts with no EFI problems at
all.

Good choice in vehicles. I just hit 120,000 miles and still going strong.

Yes, I've used one to run non-ICOM rigs for years. Mine is "permanently" moded for 230 V operation since I used it on an FG DXpedition. I run it from a 115 to 230 transformer here at home. N6AMG steered me to it as a nice small supply to take on DXpeditions.

If you call Yaesu in Ca., they sell a service manual very reasonable.
In it is covered the mods, option adding, and adding freqs. - very
detailed.... A must if you want to get serious with any of the 101's.
Doesn't cover the ZD's Mark II or III's - just the E, EE, EX & F series.
I think I paid $25.00 for mine 15 years ago an wouldn't sell it for a
$100. Fixed many a 101 with it not to mention put them back to Ham use
after being on CB band... A very complete service manual... Good luck.

1472. 5/8 (2m) wave MFJ vs. Larsen?

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-26 00:00:00 UTC
From: mouer@mail.ameritel.net
Message-ID: <41a7cc$335a.183@NEWS>
Source record: 202109

I have an HTX-202 (1 watt low, 5 watt hi).

I am looking to get a 5/8 wave mag mount ant. but I don't know which one I should get. Maybe even a 5/8 @ RadShak would be enough, I don't know and that's why I'm posting this here.

1. What I want/need to know is does MFJ, Larsen, and RS ants have magnetic mounts (~5" dia) that would allow me to exchange the 5/8 with a 1/4?

2. Which would you recommend? What would you say is the "quality/$" index?

3. What is the gain on a 1/4 and a 5/8 wave?

3. Are these calculations correct...(assume P_in = 1 watt)

3dB Gain: 10*log(Power Gain) = dB
==> P_out = P_in * 10^(3/10)
P_out = 1.99 watt

6dB Gain: 10*log(Power Gain) = dB
==> P_out = P_in * 10^(6/10)
P_out = 3.98 watt

Any info is appreciated.
Thanks.

-Dan.

> My experience with these, on the receiving end, is that while they
>work pretty well, they give the transmitter a muffled sound.

And they are totally useless if you have the sniffles, a cold or the
flu.

For best results have an ear mold made by a good hearing aid shop. The
comfort level is much improved.

And after you get comfortable with it, and build yourself a pendant-
style PTT button to drop down your jacket sleeve, you'll get strange
looks if you go to the airport, wearing a suit with the HT on your
belt and with an american flag lapel pin.
Standard question from security: "Who is coming in today?".
Standard answer: "If you needed to know, you would".

Date: 1996-04-26 00:00:00 UTC
From: "J.D. Taliaferro" <talia@use.usit.net>
Message-ID: <3180E88E.31B6@use.usit.net>
Source record: 202111

Greetings,

I'm looking for the expansion cards for an FR 101-S. Thereare three of them: The FM card, Yaesu# PB-1269; the 6 meter card, PB-1305; and the 2 meter card, PB-1306.

Please send any info as to where I could find them, price, etc.

I can be reached as follows: day 901-427-4774, night 901-658-9471
Email: talia@use.usit.net

Thanks for your assistance,

J.D. Taliaferro, KE4RKI

>help would be appreciated.

The Saturn-6 antenna, also called the Halo as I recall, had an optional impedance-matching transformer that mounted at the feed area. It attached to the screws you mentioned and had a SO-239 coax fitting on the bottom. Alternatively, the antenna came with instructions for fabricating an impedance-matching balun out of RG-58 coax. Alas, I cannot recall the details (perhaps someone else will?) but you made a "Y" of a certain length and dropped the cable assembly down the mast.

I carried such an antenna on the back of 2 different cars for years and used a much-modified Heath Sixer as a mobile rig before 2mFM was popular. Always got strange looks with that birdcage affair... some thought it was some sort of radar!

1478. Int vs. ext antenna tuners

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-26 00:00:00 UTC
From: Nat Davis <ndavis@vt.edu>
Message-ID: <4lqhfc$b3f@solaris.cc.vt.edu>
Source record: 202115

I'm considering a new HF rig and was wondering about internal versus
external antenna tuners...

Internal ones are "automatic" and would seem to be very convenient.
When an "added" cost to the basic rig, they seem to be less $$ than
external ones.

Are external tuners more versatile -- handle wider SWR ranges or power
for example? Not that I plan on changing rigs often, but it would seem
that an external one might be more cost effective in the long run
when it can be used with several different rigs.

Bottom line is: in terms of performance and cost, which is my best bet?
If you like externals, any favorite brands/models (I do not anticipate running
a linear amp)?

Thanks for you input.

Hi John.

Numerology is where you find it!

Examining the numbers listed in the "Organization" heading of your original posting, we find highly relevant information!

the numbers are: 800.444.1458

Obvioulsy the 800, being the prefix of toll free calls, doesn't count.

The 444, on the other hand, is VERY inportant. Note that each number in 444 is exactly 2 away from each number in 666!

The last sequence of numbers also contains meaning. add: 1+4+5+8 and you get 18. Note that the 1458 could be viewed as the first in the sequence of numbers, when read backwards. You can therefore add another 1, ending up with 19.

So we have a as a result the number 2, and the number 19, which, when interpreted as the positions of letters in the alphabet, give you BS, perhaps the most important thing that can be said about numerology!

Hi Burch, I never said I pay $10 for each for sale posting - just wondered if you would change your attitude if they cost *you* $10 each. Because of where he lives, my dad has to pay long distance telephone rates to download this group at 1200 baud. How do you think he likes paying for for-sale postings out of his social security check?

>Most people don't have a clue about how newgroups are distributed
>throughout the internet and this is definately not the place to
>discuss it.

Then how do you propose to educate ignorant posters? IMHO, for sale postings on this group are like fleas on my dog. It's a dirty job, but someone has to do it. For sale postings to this group are absolutely against the guidelines and supporting violation of the guidelines is destructive. This newsgroup can easily be killed by for sale and binary postings. Such acts are similar to interference on the air by hams who transmit before they listen.

Message-ID: <3180cc08.33783862@news.tfs.net>
Source record: 202121
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.swap

I have a Toshiba T-1900 laptop, grayscale b/w screen, brand new battery, 486, 4 meg RAM, 200 meg HD (uncompressed -- 360 compressed), 14.4 fax/data PCMCIA modem, charger and carrying case (Targa). I'm looking to swap for a clean TS-50 or similar mobile HF rig. Also have an external monitor/keyboard/Microsoft mouse, and Epson Stylus 400 ESC/P2 Inkjet printer that I can throw in for an HF/VHF all-mode mobile ICOM IC-706. Manuals for the computer, and the card manager software, are included.

Being an apartment dweller, would really like to go compact HF. Personal delivery can be arranged throughout the midwest and southeast (I'm in Kansas City, and for the next month or so will still be travelling through Missouri to Western Tennessee. Iowa, Southern Nebraska, Western Kansas, Eastern Oklahoma -- including OKC -- East and Northwest Arkansas, Western Kentucky, Middle Tennessee, North Mississippi, Northern Alabama are all potential areas for delivery, on my schedule!)

This computer is in excellent condition, and was used both on the road and as a primary home computer with the accessories. Reason for trade: got a new pentium at home, and have little need for mobile computing anymore.

Address/Phone number will be given out by private e-mail only, for serious inquiries. Cash price would be $950 for the laptop, $1,250 with the external accessories.

Thanks,

Marty KN4BH/0

I can't speak for the cars chip, but I have had good luck fishing
power cables through most vehicles using the rubber boot which
surounds the steering column. I poke a small hole throught the rubber
and push everything through the hole. This includes one pair of 12
gauge wires and two coax feedlines. I've done this on three
different vehicles of mine with no ill effects from water.

Make sure your cables and other connectors are well clear of any
moving parts around the steering wheel!!!!!!!!!!!

1487. RS-232 to TTL converter cables available

I've got a FT-51 too. I'm thinking of making my own adapter(s).
1. Save $35 bucks :)
2. Hook to my standard connection that I use with my moblies and home 13.8V power supply.
3. Adapt to the bottom of my small battery and fit into my small case. (So I dont have to take the case on and off.)
4. Possibly anougther connector to charge from supplied wall charger.

I've discovered the "cigar to cup" adapter is a filter, fuse, and trickle charger. My tests show it droping the voltage by exacly 1 Volt. Maybe the current is regulated into the batterys charge conections, I don't know. I do belive the battery's have current and heat protection.
My theory is Yaesu did'nt put an easy 12V connection on the unit due to size and the use of smaller (less voltage needed) batterys.
What do you think?

>As I recall, thinking back a few years: The EE model lacked some of
>the E's features, such as the RF processor, some of the 10m segments,
>and the 160m band.

At the time my EE was produced, the only difference between the E and EE was the speech processor. Frequency coverage was exactly the same (my EE had 160M and all of 10M). My unit was not modified and the coverage and features were (are) verified by the owner's manual.

>The earlier E's did have 11m capability (when the wire was clipped)
>and the FCC clamped down on Yaesu and required them to remove the
>11m circuitry in later E models, allowing the addition of a user-set
>auxiliary band. Yaesu eventually called the non-11m version the
>FT-101F, one of which I still use.

Someone wrote me in e-mail to say that their EE also had 11M on the bandswitch. However, my late model EE definitely did not. So, you are obviously right. There must have been a change in the 11M coverage of the E and EE models sometime during the production run that did not result in a model number change. This would explain the confusion on this point.

Do you know if there were any differences between the late model E and the F versions other than the model number?

This mod requires two parts. The first is to remove a resistor(s) I think (it has been a while since it did it). The second is to install two chip transistors that must be ordered from ICOM. Without those transistors you will receive nothing at all in the 800 MHz band. So if you did not install the transistors, it is acting just the way it should.

As a note, I've been waiting MONTHS for a service manual so I can spot the location for the stupid transistors. The mod book I paid so much for (Radio/Tech Modifications) isn't worth squat for trying to lcoate the boards and locations for surface mount components.

Hi Nat. An internal tuner will be fine if you are going to be using a fairly resonant antenna (say 3:1 or less) all of the time. External transmatches will give you - greater matching range, swr and power meter, built in antenna switches, and biult in balun usually if you are going to use ladder line for antenna feed. If you are going to use an external amplifier then you obviously must use a suitable transmatch. Some also have built in dummy load which may or may not be useful to you. I like one to tune up my Drake and Collins rigs without having to qrm anyone. I have owned to MFJ's and can NOT recommend that brand anymore due to problems I have had with both of them. I currently use the MFJ Versa Tuner V and found that the body the the roller inductor is on has MELTED at the far end toward the back of the tuner and I have never run more than 1000 watts on ssb - one third of the so called rated power of this transmatch. I don't know what else to recommend as of now except for the Nye Viking MBVA, but it is a $750 unit. I would like to hear from anyone who has used the Vectronics/Tucker brands and have examined them as to consruction/component quality. I bet they cant be any worse than what I have experienced with MFJ, and their prices don't seem much more. Hope I helped and good luck! --- Steve N9ROU

Not being a macintosh user, I really don't follow up on MAC software much, however I seem to recall an article a couple (maybe as much as 3) years ago about that subject. Of course it would have been targeted to a MAC Clasic or something like that, however it still may work, or something similar will, on your powerbook.

Good luck...

Hi Steve, it is hard for me to believe that anyone who reads this
newsgroup is using the built-in balun to feed other than the
characteristic impedance of the ladder line. If one is running
anything other than a characteristic impedance resistive load,
like a non-resonant length antenna, one should not be using the
built-in balun in an unbalanced antenna tuner. To advocate such
is simply bad advice.

Back in Feb 1976 there was an article published in Ham Radio Magazine
about an RTTY demodulator called the DT600. Boards could be purchased from
a company in Florida called Data Technology Inc. I am looking for someone
that purchased the board and has the schematics and could make a of copy
of them for me. I have all the documentation except for the schematics.
Thanks es 73s de Steve K1EL

Apparently pricing is different in the USA.
In Europe, a TS-790 is much more expensive than a similar FT-736 setup.

There is a kit made by S & S Engineering. Cost is about $70
Or with case and all $100. This gives you the last 4 digits of the
frequency. So instead of reading 14.204.6 you'll see 204.6... Good enough.
Anyway this kit will work with any rig. S&S engineering can be called
at 1-301-416-0661

We are a retail hardware store that has dealt in government surplus equipment over the years. Recently, we have discovered hidden away a number of pieces of equipment dating from the war years and early 1950's a number of items of old radio and electronic equipment. Some of it came from the airforce and has RCAF markings. We are not all that familiar with this stuff but am told by local ham radio buffs that some of it is of interest. If you are interested in this type of old equipment I would be happy to e-mail you the list (with prices) on an excel spreadsheet. Our e-mail address is Ribtor@cadvision.com, or our mailing address is Ribtor, 318 11 Avenue S.E., Calgary, Alberta, Canada, T2V 2M7. My name is Joel Lipkind, have a nice day.

:>newsgroup with non-issues. Lighten up! We are duly impressed with your
:>powers of observation and ability to communicate - as well as your
:>generally broad scope of knowledge. Let's move on to more interesting and
:>appropriate subjects than QST's editing policies...

YOU are the one that needs to lighten up. Tom happens to be one of the top designers of amateur amplifiers and has turned around the product line of at least two manufacturers. For him to take the time to get on the 'net and discuss the issues concerning amateur power generation without the self-serving, advertising hype speaks very highly.

Any (all) ARRL members with any amount of technical smarts have the right to expect a high degree of accuracy and integrity in their membership journal. For the editors of _QST_ to permit the President of a tube manufacturer to use an aticle about the history of zero bias triodes to promote his company's (tetrode) products and bash his competitors' products (which he can't match) violates every principle of journalistic ethics ... particularly since the problem could have been avoided by simply cutting the last two paragraphs.

In any case, your personal attack on W8JI is out of place here.

Hello! I've got some awesome news that I think you need to take two minutes to read if you have ever thought "How could I make some serious cash in a hurry???" , or been in serious debt, ready to do almost anything to get the money needed to pay off those bill collectors. So grab a snack, a warm cup of coffee, or a glass of your favorite beverage, get comfortable and listen to this interesting, exciting find!

Let me start by saying that I FINALLY FOUND IT! That's right! I found it! And I HATE GET RICH QUICK SCHEMES!! I hate those schemes like multi-level marketing, mail-order schemes, envelope stuffing scams, 900 number scams... the list goes on forever. I have tried every darn get rich quick scheme out there over the past 12 years. I somehow got on mailing lists for people looking to make money (more like 'desperate stupid people who will try anything for money!'). Well, when I was a teenager, these claims to 'get me rich quick' sounded irresistible! I would shell out $14.95 here, $29.95 there, $24.95 here, and another $49.95 there. I had maxed out my new Circuit City Card AND my Visa...I was desperate for money!! So, I gave them all a chance but failed at every one of them! Maybe they worked for some people, but not for me. Eventually, I just tossed that JUNK MAIL in the trash when I got the mail. I recognized it right away. I can smell a money scam from a mile away these days, SO I THOUGHT.... I thought I could sniff out a scam easily. WAS I WRONG!! ....I LOVE THE INTERNET!!!

I was scanning thru a NEWSGROUP and saw an article stating to GET CASH FAST!! I thought..."Here on the Internet?? Well, I'll just have to see what schemes could possibly be on the internet." The article described a way to MAIL A ONE DOLLAR BILL TO ONLY FIVE PEOPLE AND MAKE $50, 0000 IN CASH WITHIN 4 WEEKS! Well, the more I thought about it, the more I became very curious. Why? Because of the way it worked AND BECAUSE IT WOULD ONLY COST ME FIVE DOLLARS (AND FIVE STAMPS), THAT'S ALL I EVER PAY....EVER!!

Ok, so the $50,000 in cash was maybe an tough amount to reach, but it was possible. I knew that I could at least get a return of $1,000 or so. So I did it!! As per the instructions in the article, I mailed out ('snail mail' for you e-mail fanatics) a single dollar bill to each of the five people on the list that was contained in the article. I included a small note, with the dollar, that stated "Please Add Me

To Your List." I then removed the first position name of the five names listed and moved everyone up one position, and I put my name in position five of the list. This is how the money starts rolling in! I then took this revised article now with my name on the list and REPOSTED IT ON AS MANY NEWSGROUPS AND LOCAL BULLETIN BOARD MESSAGE AREAS THAT I KNEW. I then waited to watch the money come in...prepared to maybe receive about $1000 to $1500 in cash or so.... But what a welcome surprise when those envelopes kept coming in!!! I knew what they were as soon as I saw the return addresses from people all over the world -Most from the U.S., but some from Canada, even some from Australia! I tell you, THAT WAS EXCITING!! So how much did I get in total return? $1000? $5000? Not even!!! I received a total of $23,343!!! I couldn't believe it!!

I now have a brand new black Acura Integra to speak for, due to this!! Now after almost 8 months, I am ready to do it again!!! So maybe it was possible to get $50,000 in cash, I don't know, but IT COMPLETELY DEPENDS ON YOU, THE INDIVIDUAL! You must follow through and repost this article everywhere you can think of! The more postings you achieve will determine how much cash will arrive in your very own mailbox!! It's just too easy to pass up!!!

Let's review the reasons why you should do this: The only cost factors are for the five stamps, the 5 envelopes and the 5 one dollar bills that you send out to the listed names by snail mail (US Postal Service Mail). Then just simply repost the article (WITH YOUR NAME ADDED) to all the newsgroups and local BBS's you can. Then sit back and, (ironically), enjoy walking (you can run if you like! :o) down your driveway to your mailbox and scoop up your rewards!! We all have five dollars to put into such an easy effortless investment with SPECTACULAR REALISTIC RETURNS OF $15,000 to $25,000 in about 3-5 weeks! So HOLD OFF ON THOSE LOTTERY NUMBERS FOR TODAY,
EAT AT HOME TONIGHT INSTEAD OF TAKEOUT FROM McDONALDS AND INVEST FIVE

DOLLARS IN THIS AMAZING MONEY MAKING SYSTEM NOW!!! YOU CAN'T LOSE!!

So how do you do it exactly, you ask? I have carefully provided the most detailed, yet straightforward instructions on how to easily get this underway and get your cash on its way. SO, ARE YOU READY TO MAKE SOME CASH!!!?? HERE WE GO!!!

*** THE LIST OF NAMES IS AT THE END OF THIS ARTICLE. ***

OK, Read this carefully. Get a printout of this information, if you like, so you can easily refer to it as often as needed.

INSTRUCTIONS:

1. Take a sheet of paper and write on it the following: "Please add my name to your list". This creates a service out of this money making system and thus making it completely legal. You are not just randomly sending a dollar to someone, you are paying one dollar for a legitimate service. Make sure you include your name and address. I

assure you that, again, this is completely legal! For a neat little twist, also write what slot their name was in: "You were in slot 3", Just to add a little fun! This is all about having fun and making money at the same time!

2. Now fold this sheet of paper around a dollar bill ,(no checks or money orders), and put them into an envelope and send it on its way to the five people listed. The folding of the paper around the bill will insure its arrival to its recipient. THIS STEP IS IMPORTANT!!

3. Now listen carefully, here's where you get YOUR MONEY COMING TO YOUR MAILBOX. Look at the list of five people; remove the first name from position one and move everyone on the list up slot one on the list. Position 2 name will now move to the position 1 slot , position 3 will now become position 2, 4 will be 3, 5 will be 4. Now put your name, address, zipcode AND COUNTRY in position 5, the bottom position on the list.

4. Now upload this updated file to as many newsgroups and local bulletin boards' message areas & file section as possible. Give a catchy description of the file so it gets noticed!! Such as: "NEED FAST CASH?, HERE IT IS!" or "NEED CASH TO PAY OFF YOUR DEBTS??", etc. And the more uploads, the more money you will make, and of course, the more money the others on the list will make too. LET'S ALL TAKE CARE OF EACH OTHER BY BEING HONEST AND BY PUTTING FORTH 120 PERCENT INTO THIS PROFITABLE & AMAZING SYSTEM!!! You'll reap the benefits, believe me!!! Set a goal for the number of total uploads you'll post, such as 15-20 postings or more! Always have a goal in mind!!!
If you can UUE encode the file when uploading, that will make it easier for the people to receive it and have it downloaded to their hard drive. That way they get a copy of the article right on their computer without hassles of viewing and then saving the article from the File menu. Don't alter the file type, leave it as an MS-DOS Text file. The best test is to be able to view this file using Microsoft's Notepad for Windows 3.x or WordPad for Windows '95. If the margins look right without making the screen slide left or right when at the ends of the sentences, you're in business!

5. If you need help uploading, simply ask the sysop of the BBS, or "POST" a message on a newsgroup asking how to post a file, tell them who your Internet provider is and PEOPLE WILL ALWAYS BE GLAD TO HELP. I would try to describe how to do it but there are simply too many internet software packages with slightly different yet relatively simple ways to post or upload a file. Just ask for help or look in the help section for 'posting'. I do know that for GNN, you simply select 'POST' then enter a catchy description under the subject box, choose 'ATTACH', selecting 'UUE' and NOT 'TXT', then
choose 'Browse' to go look for the file. Find your text file CASH.TXT and click on it and choose 'OK'. Place a one line statement in the main body section of the message post screen. Something like "Download this to read how to get cash arriving in your mailbox with no

paybacks!" or whatever. Just make sure it represents its true feasibility, NOT something like..."Get one million dollars flooding in your mailbox in two days!" You'll never get ANY responses!

6. And this is the step I like. JUST SIT BACK AND ENJOY LIFE BECAUSE

CASH IS ON ITS THE WAY!! Expect to see a little money start to trickle in around 2 weeks, but AT ABOUT WEEKS 3 & 4, THE MONEY STORM WILL HIT YOUR MAILBOX!! All you have to do is take it out of the mailbox and try not to scream too loud (outside anyway) when you realize YOU HIT THE BIG TIME AT LAST!!

7. So go PAY OFF YOUR BILLS AND DEBTS and then get that something special you always wanted or buy that special person in your life (or the one you want in your life) a gift they'll never forget. ENJOY LIFE!

8. Now when you get low on this money supply, simply re-activate this file again; Reposting it in the old places where you originally posted and possibly some new places you now know of. Don't ever lose this file, always keep a copy at your reach for when you ever need cash. THIS IS AN INCREDIBLE TOOL THAT YOU CAN ALWAYS RE-USE TIME AND TIME AGAIN WHEN CASH IS NEEDED!

9. (This step added by Charles Reiley). Hello, This is exciting isn't it?! While I'm on the list, just add a note saying "Please include extra money tips" with your name & E-MAIL address, and I will (FOR FREE) send you some neat methods to increase the money you will receive with this plan.
Why?... Why not? I'm not a selfish jerk...I like helping out others. E-mail just makes it a touch easier and cheaper, too! After I drop off the list, I can no longer offer you this advice, obviously, but maybe someone else who gets my tips will offer and simply replace my name on this step number 9. Good luck and give this plan your all, it will definitely pay off!
Like Mike said, HAVE FUN WITH IT!!!

> -Dan.I had a mfj 5/8 wave mobel antenna and it worked almost as well as the rubber ducky ant that came with
my handheld and I could bring just as many repeaters up if I unscrewed the whip and took it off the
mount as when the whip was on the mount, after giving up in fustration trying to get the s-w-r somewhat
acceptable and trying to get the whip to show some gain over the coax and mag mount I went to the local radio
shack and tried theirs out, I put it on, the swr was good and it worked, by the way you will find that the
5/8 wave ant has benifits when trying to access distant repeaters, espically on handhelds..

>external "fuzz" devices. Contrary to your statement, the tube
>amplifier produces less odd-harmonic distortion when driven into
>clipping, in turn creating a more "natural" sound.

Clipping produces only odd order harmonics. By definition, square
waves are composed only of odd order harmonics in an infinite
power series. The output transformer in a tube amp acts as a low
pass filter and attenuates some of the higher order harmonics,
hence the "rounded" appearance of tube amp clipping, but a low
pass filter on the output of a solid state amp (Crown uses one,
calling it an ultrasonic filter) will give you the same spectrum.

Clipping in a tube amp results when power supply voltage limits
are reached, or when tube cathode current emission limits are
reached. In a transistor amp, clipping results when power supply
voltage limits are reached, or when power supply current limits
are reached. Unlike tubes, transistors don't exhibit a majority
carrier current limit effect.

Since transistor amps typically don't use an audio output
transformer, they don't suffer from hystersis effects or
saturation effects from the transformer, and the signal is
not bandlimited by the inductance and distributed capacitance
of the transformer windings. It is the presence of the iron
core output transformer that gives the tube amp most of its
distortion characteristics. McIntosh used a negative feedback
winding on their output transformers to attempt to linearize
some of these effects, but they were only partially successful.
Most tube amps don't even attempt to correct these distortions.

>
>I hope the broadcast industry will not fall victim to the low power
>myth that is being circulated in HDTV circles ("you'll only need
>about 30 KW to equal your current grabe B contours").

That's not a myth. But it also doesn't mean your transmitter will
be smaller. HDTV has a peak to average ratio of 1:1 while NTSC VSB
has pk/avg ratio of 2.8:1 (approximately, depending on picture content,
blah, blah). So while the peak power demand is less for HDTV, the
average power requirement remains much the same, IE NTSC VSB transmitters
are rated by their peak power while HDTV transmitters are rated by
their average power (which for them is the same as their peak power).
So a 30 kW HDTV transmitter should be about equivalent to a 100 kW
(peak) NTSC VSB transmitter in the average power density it puts over
a target coverage area.

It gets even better when you recall that the NTSC signal is VSB AM,
and that dead carrier carries no intelligence. The sideband power
of the NTSC transmitter has a pk/avg ratio of 8:1. That costs another
9 db at the receiver in noise margin for a "snow free" picture during
high luminance periods. (Peak white corresponds to minimum transmitted
power in NTSC.)

(This may seem counterintuitive to amateurs, but we have to maintain
the same noise margin in "quiet" passages as we do in "loud" ones,
in picture transmission, so SSB is actually a hinderance rather than
a help, IE we have to scale the system noise margin for the weakest
part of the envelope, not the strongest.)

Or your equipment! That's why you also have to account for paths
through your coaxes, control wiring, telco, etc as well as power.

>Ideally, all wiring should enter and leave the house at one point, and all
>outside grounds should connect at that same point. What this does is
>prevent ground loops and improve the ground connection.

It prevents, actually shorts out, ground loops, but it doesn't improve
the ground connection. That still depends on how good your connection(s)
are to Earth.

>Hi Tom, IMO the only advantage my IC-706 has over my IC-725 on HF
>is size. It is inferior to my IC-745 across the board.

Oooh, I wouldn't go that far. My IC-745 was *really* crummy. The
IC-706 is better than that, especially if you intelligently use
the attenuator, but I will say it isn't as good as my IC-735 in
dealing with strong signals.

For 80/160 a really sharp "antenna tuner" or preselector can be
a huge help in keeping some of those pesky Texas kilowatts from
crunching your receiver. If they nestle right up beside the desired
signal, however, you'll want something better than the IC-706 to
deal with them. (A signal seeking cruise missile comes to mind.)

Don't panic just yet, Roberto. Try an initial power up reset first.
That should get everything back to factory defaults.

Gary

Nonsense right back at you. No matter what mechanical damping you
use, you *must* allow for the damping provided by the amplifier
in your speaker enclosure design. Otherwise the system will be
either overdamped or underdamped. Since tube amps offer little
damping and transistor amps typically offer a lot, you have to
allow for that in speaker enclosure design.

>>and THD and clipping was not pretty, even on the Mc with its heavy
>>negative feedback.
>
>Clipping isn't pretty in any amp. The difference is the way the two
>types of devices clip. Tube amps create less of the odd-order
>distortion that is particularly offensive to the ears.

Clipping is a square wave generating process, and by definition
square waves are composed strictly of odd order harmonics in an
infinite power series. Tubes don't clip differently from transistors
when they hit the power supply limit (though they can also clip by
hitting the cathode current emission limit which transistors don't
have). The reason tube amps appear to have softer clipping is due
to the low pass filter effect of the output transformer. This attenuates
some of the higher order products and produces the "rounded" appearance
of the clipping. A low pass filter on the output of a transistor amp
will produce the same spectrum. Crown calls theirs an ultrasonic
filter.

>>Of course the old Bozak Concert Grands and Altec Voice of the Theatre

>
>High quality electrostatics, planars, horns, ribbons, the old Heil
>driver, and even some soft-dome midrange and tweeter drivers exhibit
>much less than 3% distortion.

A few electrostats are good, but horns produce phase distortions of
10% or more, which is why big horns like the old Altecs aren't built
anymore by anyone who cares about high fidelity. Most speaker distortion
occurs in the low and mid bass region, tweeters can be virtually ignored
when discussing speaker distortion. The near universal use of poly cones
today has reduced cone break up as source of speaker distortion markedly,
but the interaction of the speaker with the enclosure still dominates
speaker distortion (if you discount the phase distortions introduced by
multiple crossover networks).

>speakers in SPL at one watt/one meter, the size of the room and the
>SPL you consider "room filling" either at the location of the listener
>or one meter from the driver.

The span between 40 watts and 800 watts is 13 db. The dynamic range
of music is 90 db. Now a quiet room has a SPL of 62 dba while a jet
engine at takeoff has a SPL of 110 dba and 100 dba is generally
accepted as the threshold of pain. So the listening room environment
is a limited subset of the musical dynamic range, limited to excursions
of about 38 db. Depending on the musical content, you may wish to
boost the bottom end of the musical dynamic range up to greater than
62 dba in order for it to be audible. That means that if the music
has full dynamics, you'll need to reproduce 152 dba to maintain
dynamics. Obviously you don't want to do that, since it would cause
hearing damage. So you lose some of the bottom end of the range
down into room noise, and lose some of the upper end of the range
into amplifier clipping. But that still leaves you with 38 db of
dynamics to reproduce faithfully.

Now a comfortable listening level is 80 dba, and that centers you
in the usable range. If it takes 40 watts to maintain that sound
level, a dynamic transient only 13 db greater, IE 93 dba, will
require an amp with a 800 watt peak output to avoid clipping

distortion.

Many of today's speakers trade efficiency for an attempt at linearity and small size, so 40 watts average drive power is not unusual. Of course a very efficient speaker, which only needs 1 watt to maintain a SPL of 80 dba at the listening location, would only need 20 watts peak to reproduce a 93 dba transient. Few (if any) speakers are that sensitive while still remaining linear across the 20 Hz to 20,000 Hz frequency span. (They fall down on the low end of the frequency span of course.)

>Also, which speakers are "most people" using that are capable of
>reproducing the 800 watts peak that you claim is necessary?

Many speakers are capable of handling a 800 watt transient excursion. This isn't sinewave power you realize, it is a transient. The IHF has a rating scale for this. My little Polk Compact reference speakers have an IHF rating of 480 watts, which won't do the job, but then they don't need 40 watts to generate a 80 dba SPL either. Their bigger brothers, the reference series, has an IHF rating of 1600 watts and will serve nicely.

>>The other thing you can hear is the effect of improperly matched
>>damping factor.
>
>There's no such thing as matched damping factor. It's a euphemism for
>the need to minimize the audible defects of junk speakers. I suggest
>that if you think older speakers such as Acoustic Research, Klipsch,
>Altec, University and Jensen have muddy bass when they're driven by
>solid-state amps, you've been conditioned by the large amount of crap
>that's now on the market.

The audio spectrum analyzer doesn't lie, Jack. They do have muddy bass response when heavily damped by a solid state amplifier, and modern speakers sound boomy as hell when driven by an old tube amp. And you can see both of those defects on the audio spectrum analyzer as well as hear them.

In case someone is wondering what we're talking about when we say "damping", perhaps a moment's worth of explanation is in order. If you take a meter movement with open terminals and shake it, the needle will swing wildly. If you take that same meter movement and connect a low impedance across its terminals, when you swing it, the needle won't gyrate madly. Its response has been *damped* by the load placed on it (its a motor effect). The same thing happens with a speaker cone. When it is driven, it will tend to oscillate madly at its mechanical resonance unless it is damped. There are two forms of damping applied to a speaker cone, electrical as just outlined, and mechanical.

Now you can apply mechanical friction damping to a speaker cone, using its flexible support as a friction "shock absorber", but that hurts speaker efficiency and limits cone excursion, so it is rarely used today. Or you can use an "air suspension" where the air trapped in the enclosure acts as a spring against the speaker cone's piston. There is very little friction here, so the speaker can be quite efficient, and large cone excursions can be supported so bass response can be quite good, but you need some other method of damping the cone's resonance. This is done by adjusting the enclosure's volume so that it is anti-resonant at the cone's natural resonant frequency, IE it will return a negative pressure wave reflection to the cone at the time the cone is trying to produce a positive pressure wave, and vice versa. This will damp the cone response. You can also use tuned ports, ducts, or pipes to achieve the same effect.

No matter what type of mechanical damping you use, it is the *sum* of the electrical damping and the mechanical damping that must precisely cancel the self-resonant oscillations of the speaker cone. Change either one, and you have to make a corresponding change in the other to maintain precise damping. Speakers designed to be driven by tube amps have a lot of mechanical damping to make up for the small electrical damping the tube amp offers, and speakers designed to be driven by transistor amps have relatively less mechanical damping to accomodate the larger electrical damping the transistor amp offers.

The electrical damping offered by an amplifier is a function of its output impedance. A transistor amp typically has an output impedance which is a fraction of an ohm. A tube amp has an impedance, determined by its output transformer ratio, which is typically 8 or 16 ohms. Thus a transistor amp has many times the damping of a tube amp, and needs a speaker with many times less mechanical damping.

Gary

I don't know if they are identical internally, but functionally, the AH-2 and AH-3 tuners are equivalent. The AH-2 has an external controller that connects to the rigs computer interface and ALC lines for control while band changing and tuning up. This interface is used with rigs such as the IC735. Most newer ICOM (IC737, etc) rigs have the ability to control the tuner directly thru a four pin molex connector that matches the one on the AH-2. I'm using an AH-2 with a 737 and it works just fine. When the AH-2 is plugged in, the 737's internal tuner is disabled.

Have not tried it, but think you could go ahead and use the external controller with these newer rigs, in which case any internal antenna tuner would still function, giving and even wider matching range.

I don't think extending the control cable a reasonable amount would be a problem.

Tom)23 Apr 1996 07:21:44 -0400 writes:
:>
:>Anyway, what was the grid bias of the tube and class of operation? Did the
:>author include a screen meter? Was there an energy storage component at
:>the screen to improve dynamic regulation during voice peaks?
:>

The control grid is biased at -56 Volts. The article does not make any
reference to operating class of the tube (the data packet from ARRL does
not provide the information either).

The MLA-2500 grid current position on the multimeter was converted to
read screen current (60 mA full scale). The screen uses a regulated
supply (voltage doubler from the 120 volt transformer winding to a
zener diode/pass transistor regulator). I have no idea how the
regulator
performs under dynamic conditions.

:>I find it strange that all these tubes require a 50 ohm grid resistor to
:>develop correct grid voltage swing with a 100 watt exciter. That almost
:>seems too good to be true. I am trying to help three people get 4CX1600's
:>running.

The article looks "formula" in that it simply uses a 50 Ohm grid
resistor
rather than matching the grid resistor to the operating class and using
a
resistive "L" pad (or other attenuator) to match the available drive.
Such a design would also allow the modified amplifier to be "scaled" to
match 100 Watt rigs, 150 Watt rigs or 200 Watt rigs (FT-1000).

:>Tetrode circuits are a real design pain compared to triodes, and I've
:>never seen any of the "marketing tools" the author has gotten published
:>properly address tetrode design.

The conversion article wasn't written by Badger. However, the author
does
acknowlege his assistance. I suspect some of Badger's "tetrode centric"
view is due to the fact that his company doesn't make 3CX400/8874,
3CX800,
3CX1200 or 3CX1500A7/8877 devices. I suppose the additional complexity
of
proper tetrode design isn't as much of a burden in industrial
applications
where the operation is at a single frequency and consistent power level

(RF heating, etc.). There one needn't be as concerned with input
matching
over a wide frequency range or IMD.

>comments???? de WA3KQA

You have to keep the board powered up while you replace
the battery, else you'll lose the contents of the RAM
(which contains the radio's operating program). Be careful
not to short anything, and don't use a grounded tip soldering
iron (or if you do make sure the power to the board is floating
with respect to ground, IE a battery pack).

If you manage to short something and dump the memory, Icom will
reprogram it for you (for a fee, of course).

Gary

>I'm in the market for a dualband radio. I would like to hear any
>comments (both negative and positive) about ICOM, Kenwood and Alinco
>dualband radios. One point of interest is the intermod rejection
>comparison and receiver sensitivity.

All three have too much receiver sensitivity, and are too prone to
intermod (the Kenwood is the worst of course).

>Important options:
>1) Crossband Repeat

The Kenwood and Alinco have it for sure, I think the Icom does too.
It's important to be able to set separate CTCSS tones on the two
channels during crossband operation, IE has separate encoder and
decoder, make sure the radio you choose allows that.

>2) 9600 Baud

The Kenwood *clains* to be "9600 ready", but it isn't. The others
aren't either. The synthesizer designs don't allow proper 9600
baud modulation (the loop filter chops off parts of the modulation).
You can sort of make them work, but they won't work right. You either
have to go in and modify them for two point modulation, or choose
a radio that does modulation outside the synthesizer loop, IE IF
modulation such as the Azden PCS9600D and IC820H use.

>3) DTMF memory

Don't know about that, don't use it and didn't look.
Take a look at the Standard dualbander. It is almost
intermod free, and works better (but still not right)
for 9600 baud packet than the ones you've chosen.

>
>In any case, your personal attack on W8JI is out of place here.

With all due respect, Joe, it was Tom's taking a flamethrower to
the article, author, and QST from message one on this thread which
has led to all the heat and personal attacks that have followed.
That may not excuse the responses, but it is certainly reason to
have expected them.

And worse, Tom attacked the MLA2500 modification article (by a
different author) *WITHOUT EVEN HAVING READ IT FIRST*. That was
unprofessional in the extreme. It would *appear* that Tom harbors
an unexplained grudge against Svetlana and its products. Perhaps
they wouldn't give him promotional samples, hmmm?

Now I've read this article over and over trying to find what
has Tom and a few others so upset. Frankly I can't find it.
While titled as a history of the 811A, from page one other
tubes are mentioned to put the 811A in historical context.

The last two paragraphs do not differ in this regard.

And particularly I see no insult made or implied to Eimac or its products. In fact just the opposite, we find that Eimac and its products are praised many times in the article, with nine full paragraphs devoted to their products, and not a single bad thing said against them. That might be grounds for comment since the author was at one time an official of Eimac, but Tom has been strangely silent on that subject.

Tom clains there is false technical data in the article, but try as I might, I find no falsified technical data. In fact, there is very little technical data in the article at all, being as it is a historical overview and not a spec sheet comparison. The author does suggest in the last paragraph that a return to tetrode amplifiers may be more economical today given the 9 (or 10) bands that may need to be covered, and given the improvements in bias supply designs made possible by solid state components.

I don't find that a remarkable claim, and indeed the MLA2500 construction article in the following issue of QST does quite a bit to give it credence. The ARRL lab data shows that the converted amplifier has better specs than the original while using a much less expensive tube. That seems like a good deal to me, and offsets the minor complexity engendered by the need for bias supplies.

Of course perhaps I should disclaim my bias here by noting that I've worked with high power tetrode amplifiers for 30 years in broadcasting, and have come to respect them and expect quality performance from them. They routinely offer a combination of linearity, high power gain, and economy of operation that I have rarely found with stable triode amplifier designs. An examination of the tetrode equation (in Eimac's own book) should make the reason for that abundantly clear.

: >ferrite toroids. This link prevents RF injection into the mains, but
: >makes sure that my set is grounded to the mains earth. There is no direct
: >connection between the rig and the mains earth apart from this.

: While this may be the thing to do in the U.K., I would recommend
: against it. From the wiring faq (misc.consumers.house, sci.answers,
: news.answers, and other places):

: Furthermore, there should only be one grounding system in
: a home. Some codes require more than one grounding electrode.
: These will be connected together, or connected to the neutral
: at a common point - still one grounding system. Adding additional
: grounding electrodes connected to other portions of the house
: wiring is unsafe and contrary to code.

: Your connection connects extra grounding electrodes to the wiring
: of the house. The FAQ is written for North America (U.S. and Canada),
: but I would suspect that multiple ground (earth) connections is
: inappropriate for good reason. Your connection through a toroid
: is a fairly direct connection at power line frequency.

: Alan

Keep in mind that he is talking about an RF ground, which is very much
different from a DC or mains ground. If the DC/mains ground is to be
pressed into service as an RF ground, it may not work. Consider, if
the ground wire, including that in the wall, froim the radio to the
actual ground point is a quarterwavelength of the operating frequency,
the wire will act as a transmission line and transform the low
impedence at the actual ground point to a high impedence at the rig.
While the rig may be safely grounded for mains/DC, it will at the same
time be well above ground potential for RF.

Apparently, the FAQ referenced does not consider RF grounds. However,
all is not lost as there are a number of clever ways to provide a good
RF ground that is not tied to the mains ground and in fact is a
lousy mains ground! The trick is that what is a good ground at DC or
50/60Hz may be a transmission line at RF and needs to be handled as such.

Racal 6790/GM receiver for sale. Excellent condition, 7.9, 3.4, 1.6,
5 filters +SSB. RS232 interface with connector and serial cable.
Radio tunes from 0-30MHZ, tuning and LCD readout to 1hz. Selectable
AGC threshold and times, All mode including FM (ISB optional),
built-in test system which calibrates filters.
Comes also with complete operation and maintenance manual.
Radio is rack mountable, appprox 19"w x 6-1/2"h x 20"d.
Can be computer controlled using terminal program , or one such as
Visual Radio.
Asking $1500 plus shipping. (Tucker Electronics was selling for
$1500 without RS232 interface and fewer filters.)
A really great radio for LW and VLF DX, too.

Please reply via E-mail ifinterested.

Dan,

Don,t waste your money! You are going to get the Larsen now or after you've given up on the other two antennas you mentioned. So I say get it now and save money in the long run.

I f you really want a good signal, go with a through the roof installation with Larsen equipment. If you live in the city use a 1/4 wave, otherwise install the 5/8.

Date: 1996-04-28 00:00:00 UTC
From: cdorn@gpu.srv.ualberta.ca
Message-ID: <4m0h1n$tq4@pulp.ucs.ualberta.ca>
Source record: 202045

Hello,
I am looking for info and/or experience with the Drake SW4A and the
SPR4. I have a Drake catalog from 1977 listing the SPR4 and its specs,
and it looks interesting. Any comments on performance, current
availablity, and prices?
I don't have a lot on the SW4A. I understand that it came out in 1966,
and I am guessing that it was modeled on the R4A. Is that correct?
Obviously it is a tube RX, but how was the performance with this one?
Again, I am interested in availablity and prices for the SW4A.
Thanks very much,
Chris VE6RDC

Source record: 202046

I have purchased the FT-50R and yes it is a pretty cool little
"radidio". I does have a built in game if yo press the MR button
while turning the radio on. I have also modified the radio to transmit
out of band.. MARs and CAPs ...Here is the information everyone needs
to modify it:

1. remove the battery pack
2. remove the two screws contained under the Battery safety sticker
on the back of the radio.
3. remove the key board (instuctions on how to remove the keyboard are
in the owners manual)
4. by removing the keyboard, it will reveal three jumper pads 1,2,&3
5. Only jumper pad #1 will be bridged by soldier.
6. remove the soldier from jumper #1
7. now, put the radio back together
8. reset the master cpu... instruction in owners manual.
9. reset the extended receive,.. see the owners manual.
10 you now have a modified radio.
any questions e-mail me

1576. Low Transmit Audio IC-2410

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-28 00:00:00 UTC
From: flanagan@genie.com
Message-ID: <4m0rtg$86f@rock101.genie.net>
Source record: 202053

The ICOM 2410 is well-known for having low transmit audio with the stock microphone. Apparently ICOM was trying to reduce background noise by forcing the user to all but shout into the microphone.

I read an early review where the reviewer replaced the stock microphone with another standard ICOM mobile mic and found the transmit audio was back up where it "should" be. I cannot find that review. Can anyone identify the other ICOM mobile microphones that can be used with the IC-2410 to bring the transmit audio up? Thanks!

Maurizio:

I have a high-gain DX-88 sitting in my basement. I used it for about 1 year, and concluded that in all but a few circumstances, a G5RV dipole at 10 meters high is a better antenna.

The DX-88 is a good omnidirectional antenna for 10, 12, 15, 17 and 20 meters. The 40 and 80 meter performance was marginal, at best. I didn't install any ground radials, which is recommended for this antenna. Installation was easy; my antenna was ground mounted. It took me about two hours to put the antenna together, but I could do it again in 25 minutes (experience!).

My impression of this antenna is that it's a good compromise if you can't put up a dipole; however you must have ground radials if you expect to transmit on 40 and 80 meters. You should ask around about the R7 and GAP verticals, as well. Good luck, Maurizio.

Source record: 202055

::::::::::::::> MIL-SPEC PJ-068 MIC PLUGS <::::::::::::::

Original PJ-068 (Littel-Plug) microphone plugs manufactured by
Kings Electronics.

These are NOS units made in accordance with MIL-P-642A
and are supplied as original equipment to the US military
and Collins Radio.

Highest quality materials and advanced molding technique
provide firm internal interlock. Parts will not shift in
position. Screw terminals.

Black plastic handle inscribed with the following
lettering:

KINGS
PJ-068

These plugs fit Collins, Drake, and others that specify
a .206" 3-conductor phone-type mic plug.

These plugs retail for about $14 + shipping (if you can
find them!)

My price: $7.50 each (I pay shipping)

>Chris VE6RDC
>

The SW-4A covered LW, MW, and the international shortwave broadcast bnads. Unlike the SPR-4, the SW-4A was AM only and does not have the capability to add extra frequency ranges. On the shortwave bands the radio used the same IF as the R-4A, but the vfo in the SW-4A is solid state.

Source record: 201915

>>
Hi Folks, just bought a used HT-202 used but sans manual. I'm going
crackers
trying to figure out how to open the AA battery pack to install battery's.
Also in the dark as to how long to charge the NiCad pack for.
Yet another quetion, can the Charger be used as the Ext Power source that
can
be plugged into the top of the radio?
<<
To open the Alkaline AA battery pack (which I use to hold more NiCads)
just press down on the metal part (the top part) while holding the pack by
the sides. The inside (and bottom) will come out. It only goes back in
one way... so be gentle when you put it back together. If it doesn't go
in easily, put it in the other way.

The NiCad pack gets charged for about 14 hours using the RS trickle
charger that comes with the radio.... this is pretty typical of NiCads.
The little screws at the bottom of the pack are for a drop in charger..
dunno how long for that.

The charger canNOT be used as a power source for the radio, it does not
supply enough juice.

Radio Shack sells the manual for the radio.. dunno how much it costs, but
it is probably just as cheap as copying it (and less trouble)

There have been some postings about other functions... check out the
postings in this group (rec.radio.amateur.equipment, if not cross posted)
and the rec.radio.amateur.misc group.

> The radio output is only 25 W...I think that the radio is
> broken because adjusting the power output to H is only give > me 25 Watts !!

Roberto:

I am only a week into my "rice box," but in case it helps...

I assume you are not seeing 100 W on CW or SSB modes and that you know how to measure it correctly. You may not know that the output power is adjustable/settable for EACH band via the Q menu (Q for "quick set"). Make sure the Q menu is set for high power on each band (change the VFO freq to a given band and then go to the Q menu by pressing and holding DISP button--press DISP to get out of the Q menu). If you see "MEMO" in the display, you are in memory mode, not VFO mode. Power output is also adjustable/settable for each memory channel by going to Q menu on a given memory channel.

If above doesn't get you back to 100 W, even into a dummy load (anything more than 2:1 SWR will also automatically reduce power output), I am clueless as to the cause.

Good luck & 73

Bryan:

There are some shareware programs like LogEQF which support the Icom CI-V interface. I just ordered a hardware interface kit from JBI (800-524-8658). This kit connects serial PC port to radio and includes several shareware programs like LogEQF which JBI says will work with the Icom interface. Ergo, it seems there are programs available, but I can't name them for you (just yet).

I am posting this to another newsgroup in hopes someone may have more specific recommendations.

The Curtis chip has a number of 8044ABM, and is available from
Mouser Electronics ($19.95), but that doesn't sound like the same
chip. It's a 20 pin narrow DIP package. Jade sells a complete
keyer based on the Curtis chip for $39.95. A quick search didn't
turn up Logikey, is that the company name, or just the name of
the keyer?

>
>73, Moritz DL5UH

Shame on you, Moritz! Lets not contribute to another spatter generator
with such myths.

There's no need to use an amplified microphone unless your radio has
insufficient audio gain to achieve a satisfactory modulation level
with its regular microphone. In other words, if you turn the radio
audio gain all the way up and still don't have full modulation with
the regular microphone, then an amplified microphone may be required.
More likely, however, is that something is broken in either the regular
microphone or the radio and you should repair the fault instead of
bandaiding it with a "power mike". The factory was smart enough to
match the microphone supplied to the radio requirements. The power
mike will most likely simply overload the radio audio circuits and
cause a great deal of distortion products to be generated.

You won't talk further, but you will be less intelligible, and
your "spatter" will disrupt communications on adjacent frequencies.

Some radios do indeed use an amplified microphone, however, and the
microphone supplied by the factory already has the amplifier in it.
If you want to change to another type of microphone, in this case
it would be necessary to use an aftermarket amplified microphone.
Certain Icom radios fall in this category, and the Icom SM-6 is
an example of an amplified stand microphone. It works well with
the radios for which it is designed, but could overdrive radios
that do not require an amplified microphone.

And in the case of certain elderly radios which were designed for
high impedance high output crystal microphones (like the original
D-104), you may need to use an amplified microphone when you replace
the element with a more modern type (that's the purpose of the
amplified D-104). Condenser microphones are very low output, and
also generally require an amplifier to allow them to be used with
a transmitter. And, an amplifier can be used merely as an impedance
matcher to allow low impedance elements to be used with transmitters
requiring high impedance microphones (or vice versa). But in this

case it is not so much gain you are getting as a proper impedance
match.

Unless your application falls into one of the special purpose
categories mentioned, and unless your radio came with an amplified
microphone, you probably should *not* try to use an amplified
microphone with it. Consult your owner's manual. If the microphone
input is specified as -50 dbm 600 ohms, then you do *not* want
to use an amplified microphone with it. However, if the spec
is for -30 dbm 600 ohms, then you *do* need an amplified microphone,
and the factory should have already supplied one with the radio.

Set the offset *before* you store the frequency in memory.
The offset will be stored with the frequency.

Gary

>time with them as an IF unit, I'd like to improve them. Any ideas?

Well, this radio has practically no preselector filtering, but if your
transverter does, this may not be an issue. And the first stage has a
low intercept, but if your transverter has conversion loss, this may
not be an issue either. And the IF filters aren't very tight, but if
the signals you're going to receive have a good noise margin, this
may not matter either.

If points one and two aren't true for your transverter, then an
external 2m bandpass filter should be used. And you may want to
add a simple pi attenuator internal to the radio to limit the
amount of signal the receiver sees. If point 3 isn't true, you
may want to fit a tighter IF filter.

I'd give it a try as is first. You might be surprised. The
transverter may already cure most of its ills.

>watts.

The 54.77 volts is RMS of course. Drive is stated as 60 watts, and
54.77 volts is the correct RMS voltage for 60 watts across 50 ohms.
The peak voltage would be 77.22 volts. You are incorrect, however in
stating that the peak voltage can only be 56 volts for AB1 because
you've neglected the cathode resistor. There is a discrepency between
the text of the article and the diagram here. In the text, a 30 ohm
cathode resistor is called out, but on the diagram a 20 ohm resistor
is shown. Going with the value in the text, and the stated 550 mA (RMS)
of current drawn by the tube at 60 watts drive given in the parameters
table, we find that the cathode is raised above common by 16.5 volts (RMS)
or 23.26 volts peak. Added to the -56 volts static bias, that gives
79.26 volts between grid and cathode. So the 77.22 volts peak drive
is still within the correct range.

>Your data is either inaccurate or incomplete.
>
>NONE of your text about IMD makes any sense at all. How can the third
>order products be 68 dB down, and why is the two tone IMD rated in
>frequency and not product order?

Obviously, the 68 db product for a *single* tone, is the third
harmonic level of the amplifier when driven CW fashion. Product
in this case may be a poor choice of words. It is a product of the

amplifier, but it isn't a product in the conventional mixing sense.
This isn't IMD. The IMD number is for the two tone test, of course.
The first two products in that case are spaced at 2 kHz and 4 kHz
from the (suppressed) carrier frequency, and are -38 db and -48 db
respectively.

>Perhaps you have harmonics confused with second order products and IMD?

From context, it should be obvious what I meant, but I do admit I
didn't phrase it well. Look at the plots yourself at oak.oakland.edu.

>>>Tetrode circuits are a real design pain compared to triodes, and I've
>>>never seen any of the "marketing tools" the author has gotten published
>>>properly address tetrode design. Of course that may be because I have

>>>Ox that was gored, or a tempest in a tea pot, or a bad hair day".
>>
>>It certainly must be, since you don't have a technical leg to stand
>>on with your criticisms of the articles.
>
>Gary, I usually try to refrain from responding to personal comments, but
>this is really too much. Let's talk about a "short technical leg".
>
>You (incorrectly) made the following statements:
>
>1.) Tetrodes are cleaner than than triodes.

They generally are. Let me select the best tetrode amplifier for
a given power gain and you choose the best triode amplifier for
the same power gain, and I'll wager the tetrode will be cleaner.
Of course you can find examples of dirty tetrode amps and clean
triode amps, but I can equally point to dirty triode amps and
clean tetrode amps. When you choose the best of each for a given
power gain, however, I maintain the tetrode will win. That should
even be obvious if you compare the triode and tetrode equations.

>2.) VHF operators are more skilled than HF operators.

I believe that to be true, for VHF operators using high power
vacuum tube amplifiers. That's mostly EME and MS types, who
generally have built the amplifier themselves (there being
very few commercial amplifiers to purchase). I would claim
that they are likely to be more knowledgeable about the operation
of their amplifiers than someone who burned the plastic for
an Ameritron and twisted the knobs for maximum smoke (the more
typical case among HF operators as you stated yourself).

>3.) VHF amateur amplifiers have tighter IMD restrictions than HF amps.

Indeed, spelled out in 97.307 (d) and (e). Spurious products must
be down 40 db for HF amps and 60 db for VHF amps. Don't blame me,
the FCC makes the rules.

>4.) You calculated the drive power of a simple grid driven tetrode
>incorrectly, probably because you confused peak voltage and RMS drive
>voltage.

And you ignored the cathode resistor. I admit I should have gone
into exhaustive detail, as I have this time, on the grid voltage
situation, but your comments were flawed by the false assumption
that 56 volts was the total potential difference between grid and
cathode. (And I *told* you there was a cathode resistor in the
circuit.)

>It would be niceif you were a little gentler with personal comments,
>especially while making such wild technical and factual errors! If you
>have a technical disagreement, state your point with facts. Childish and
>immature personal cliche's have no place in a technical discussion.

Is that the pot calling the kettle black? It was your wild, vicious,
and totally unwarranted attack on the integrity of the QST editors
and the author of the tube article that led to a pointed response
in kind. And indeed, while I may have been casual in reporting about
the MLA2500 modification article, you admit *YOU HADN'T READ IT AT
ALL* when you lit in with more unwarranted and baseless criticisms.

>73, Cecil, KG7BK, OOTC (not speaking for my employer)

Point taken, but like I said before, many people don't have access to ALL of the ham radio groups so they CAN'T always post to the correct newsgroup. If you don't want to read certain topics, put them in your kill file and don't download them (there are several FREE newsreaders that do this.) If everyone had access to the same newsgroups, I would agree 100% with you. And since this message is off topic, I am not going to post about it anymore.

P.S. My internet provider only has around 3500 newgroups out of the 16000 that are available through the internet.

Hi Joe,
In article <4ltbpa$2i4@ram2.ramlink.net>, subich@ramlink.net (Joe Subich)
writes:

>The control grid is biased at -56 Volts. The article does not make any
>reference to operating class of the tube (the data packet from ARRL does
>not provide the information either).

The peak grid-cathode RF voltage can not be allowed to exceed 56 volts.
That requires a grid-cathode resistance of around 18 ohms for 90 watts of
drive. The correct AB1 formula for a simple shunt grid resistance is: R=
Eg^2 / 2Pdrv

A 50 ohm L pad can be calculated using ohm's law: .707bias / sqrt(p/50) =
Rgrid. The input series R would of course be: 50 - Rgrid = Rs

With 90 watts and 56 volts of bias, 30 ohms of grid-cathode shunt
resistance fed by a series 20 ohm resistor would provide both proper grid
resistance and exciter loading.

>The MLA-2500 grid current position on the multimeter was converted to
>read screen current (60 mA full scale). The screen uses a regulated
>supply (voltage doubler from the 120 volt transformer winding to a
>zener diode/pass transistor regulator). I have no idea how the
>regulator
>performs under dynamic conditions.

That would be interesting to see. A two tone test may not show
irregularities in screen dynamic regulation that cause splatter with voice
peaks.

>The article looks "formula" in that it simply uses a 50 Ohm grid
>resistor
>rather than matching the grid resistor to the operating class and using
>a
>resistive "L" pad (or other attenuator) to match the available drive.
>Such a design would also allow the modified amplifier to be "scaled" to
>match 100 Watt rigs, 150 Watt rigs or 200 Watt rigs (FT-1000).

>proper tetrode design isn't as much of a burden in industrial
>applications
>where the operation is at a single frequency and consistent power level
>(RF heating, etc.). There one needn't be as concerned with input
>matching
>over a wide frequency range or IMD.
>

Another concern of mine is that many exciters actually get "dirtier" when thee output is reduced. My IC 751A, FT-1000D, Yeasu 747, and IC-706 all show decreased IMD performance at very low exciter outputs. Plus ALC overshoot becomes a problem.
Using the wrong grid resistor is foolish, I'm surprised no one looked at the correct method of selecting the resistor.

73, Tom

Hi Gary,

You've made a small error with peak voltage or Ohm's law Gary.

>This amp requires 60 watts of drive. That's 54.77 volts across the
>50 ohm grid resistor.

That's incorrect. In AB1 the peak voltage can be 56 volts with 56 volts of bias. The RMS voltage (assuming an RF drive signal free of harmonics) is .707 times 56 volts, or ~40 volts. That is 32 watts of drive Gary, not 60 watts.

>Then perhaps you should look at the ARRL lab test data on the conversion
>(available on oak.oakland.edu). Second order products are down 50 db and

db
>at 4 kHz from the carrier. Not too shabby for a simple untuned input amp,
>and better than the MLA2500 did with the original pair of 8875 GG
triodes.

Your data is either inaccurate or incomplete.

NONE of your text about IMD makes any sense at all. How can the third order products be 68 dB down, and why is the two tone IMD rated in frequency and not product order?

Perhaps you have harmonics confused with second order products and IMD?

>>Tetrode circuits are a real design pain compared to triodes, and I've
>>never seen any of the "marketing tools" the author has gotten published
>>properly address tetrode design. Of course that may be because I have
"an
>>Ox that was gored, or a tempest in a tea pot, or a bad hair day".
>
>It certainly must be, since you don't have a technical leg to stand
>on with your criticisms of the articles.

Gary, I usually try to refrain from responding to personal comments, but this is really too much. Let's talk about a "short technical leg".

You (incorrectly) made the following statements:

1.) Tetrodes are cleaner than than triodes.

2.) VHF operators are more skilled than HF operators.

3.) VHF amateur amplifiers have tighter IMD restrictions than HF amps.

4.) You calculated the drive power of a simple grid driven tetrode incorrectly, probably because you confused peak voltage and RMS drive voltage.

It would be niceif you were a little gentler with personal comments, especially while making such wild technical and factual errors! If you have a technical disagreement, state your point with facts. Childish and immature personal cliche's have no place in a technical discussion.

Anyone,

Iv'e seen the ICOM 706 and it looks pretty cool.

before i spend my money can anyone give me any comments on it.

Mike

The advantages of using an amplified mic are a stronger, more audible signal, if your radio isn't capable of providing sufficient audio gain on its own. Most current radio equipment doesn't need to be driven with amplified microphones, however if you have a soft voice, it might help.

As far as increasing your transmitter range 10 fold, I don't agree. In order to double your effective signal strength, you must quadruple your effective radiated power. It's unlikely that an amplified microphone would do that, unless your audio input from a non-amplified mic is extremely low.

Hope this helps!

These are the ones that I know will rx in the 800MHz area......
Icom w2a
Yeasu ft-530 (older versions)
Standard c-568
Kenwood 78
The rx sensitivity is marginal on most of these, and If you are buying
an ht so you can listen to 800, I recommend an 800MHz radio. Standard
has a HX-580 that will do all types of trunking.

Elmar,
I've been using nothing but Kenwood rigs in my home station since
the early 1980s. I have used non-amplified low-Z dynamic mics,
non-amplified electret condensor mics, and amplified dynamic mics.
All of them worked fine and provided plenty of audio to drive the
rigs to full output power. Based on this experience, I'd suggest
that, if you have a non-amplified mic that you're considering using
on your rig, use it. Don't bother buying an amplified mic. Save
your money for other things.

Sorry John,
But I think that is RS best kept secret...been looking for a year
and haven't seen or heard of any yet...
Was hopeing to be able to mod/upgrade to Htx-242 specs but so far nothing
..been talking to a few RS reps that would also like to see a factory
authorized upgrade for a reasonable fee...RS would make money and we
the consumer would have better radio.

BTW: the htx-242 is jjust like the 212 but has a few more memory channels
and the ability to put out-of-ham-band freq recieve in memory, <which
in the Htx-212 could only be put in Vfo memory>.

1624. Re: intermod vs overload

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-29 00:00:00 UTC
From: 73573.1504@compuserve.com
Message-ID: <4m3021$2eg@nntpa.cb.att.com>
Source record: 201995

Let me add my $.02 worth to this discussion.

Intermods (an abbreviation for intermodulation distortion products) is caused by the mixing of 2 (or more carriers) to produce a sum and difference product. The mathematical relationship for the frequency of the intermodulation products can be expressed as follows:

fi = (m x f1 + n x f2)

where

fi is the frequency of the intermod product
f1, f2 are the frequency of the 2 carriers
m, n are positive or negative integers

m + n is called the order of the intermodulation product.

The third order intermodulation products are the most troublesome because 2 carriers that are in-band can produce an intermod product that is also in-band.

For instance, 2 strong UHF carriers carriers at 443 and 444 Mhz produce third order intermod products at

f = -1 x 443 + 2 x 444 = 445 Mhz and
f = 2 x 443 + -1 x 444 = 442 Mhz.

These intermod products are also within the ham UHF band and therefore will not be filtered by any of the filters within the receive circuitry of the radio. They will appear at the IF portion of the receiver just as any other carrier and if the real carrier at that frequency is weak, interference will result. The mixing of the 2 carriers can take place at any non-linear portion of the receiver, but the most likely place is at the mixer. The only solution to the problem is to select a mixer that produces intermod products whose amplitudes are low enough not to cause interference. These high level mixers are generally bigger in physical size and also require a higher drive level for the LO. The higher drive level for the LO requires more amplification, places more current drain on the battery, and etc. All of this contributes to a bigger more expensive radio, so careful tradeoffs are required.

The important thing to keep in mind is that if the interference is truly being caused by intermods more filtering is generally not a fix.

Sorry for the length of this follow-up, but I wanted to be thorough. I will leave it to others to give a good explantion of receiver overload. My understanding is that it is due to a very strong signal

overcoming the filtering in the receiver and showing up in the output.

1625. Re: Low Transmit Audio IC-2410

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-29 00:00:00 UTC
From: kjones@sun-link.com
Message-ID: <318509c4.184959239@news.netrax.net>
Source record: 201996

Once upon a time, flanagan@genie.com wrote 12 lines on the subject:
Low Transmit Audio IC-2410; here's some of it:

>The ICOM 2410 is well-known for having low transmit audio with the stock
>microphone. Apparently ICOM was trying to reduce background noise by
>forcing the user to all but shout into the microphone.

Well known? I have two of those beasts, and never have had a
complaint of low TX audio. On the monitor, I see peaks at five, and
slight clipping evident (IOW, perfectly adjusted) when I use the
microphone sideways at the corner of my mouth. Nothing on the radio
but me. Just like it needs to be.

What kind of working distance do you like? I've always close talked
palm mikes, but always to the side (across the face, not into it).

I NEVER false the DTMF decoders on any local repeater, not something
I can say for the Kenwood users, whose sets seem to have Loads of
Gain in the speech amp.

Source record: 202000

What's going on here folks? I have been following this list for 6 months or more on more or less regular basis. My observation was that about 50% of the traffic was FS, WTB, or NEED. So, wanting to unload my TS140, I posted it here only to get blasted by some character calling him(her?)self "Ham Burger" and told to take it to another group.

Is this a moderated group? If we're not supposed to buy/sell here, how come about 50% of the traffic is for that purpose? I have to say that email from an anonymous remailer with the nickname "Ham Burger" doesn't have much credibility with me. At least if I do post incorrectly, my call sign is hanging out there for all to see.

Hi Folks, just bought a used HT-202 used but sans manual. I'm going crackers trying to figure out how to open the AA battery pack to install battery's. Also in the dark as to how long to charge the NiCad pack for.
Yet another quetion, can the Charger be used as the Ext Power source that can be plugged into the top of the radio?

Lastly anyone have a manual for the HT-202 they'd be willing to Copy for me? I'd be happy to reimburse for the copying and shipping. Thanx folks.

I can't answer any of your specific questions, but here is my comment on
the Larsen antenna.
I bought mine at HRO and the salesman said the whip was pretuned, so I
don't have to cut it or anything. Howexer, after checking it out, the SWR
was around 2.5:1 and the lowest point SWR (1.1:1) was happening around
133MHz. I started cutting down the whip, and by the time I was done, I got
the SWR @ 146MHz down to 1.1:1 . So either A) the salesman didn't know
what he was talking about B) Larsen tunes thier whips lousy, or C) the
salesman handed me the wrong whip.
I have a feeling it was C or maybe A, but now that everything is all tuned
up, there is a night and day difference between the rubber duck and the
mobile antennas.
Good luck
-BP

Your going to have to hard re-set the tnc. See page 105 of the manual. If
you don't have the manual do the following:

Turn off unit.
Open the KPC-3.
Locate the hard reset jumper (J7). They are labled on the board.
Place jumper on BOTH pins.
Apply power to tnc.
Observe the display, it should say Checksum OK
Ram O.K. xxxk BYTES
Clock not present
replace test jumper.

Now turn power off.
Return jumper J7 to normal position (one pin only)
Put cover back on.

Your terminal program has to be set for 1200 Baud.

You'll have to re-do your settings after that.

Others may say to send a certain code to the tnc. I tried this and it did not
work. So I had to resort to a hard reset.

Hope I've helped!

There are email-news gateways that let you post to ANY group, even if your
site doesn't carry it. Try sending a post to <news-group>@cs.utexas.edu
Substitute say, rec-radio-swap for <news-group> (note the . to - transposition).
And post first to a test group to verify it.
Just be sure you tell the readers to respond via email!

To extend the TX (RX is already extended) do the following:

1) Remove the 4 screws that hold the back cover of the unit on.

2) CAREFULLY pry the case apart (It's helps to remove the VFO/Mem/etc knob first)

3) On the FRONT portion (DTMF Pad) of the case, in the upper right-hand corner you will see a BLUE wire. Cut that carefully.

4) Reassemble the unit.

5) While holding the FUNC key, press POWER to reset the unit.

6) Viola! You know have extended TX!

Hope this helps all DJ-5GT users.

Sincerely,
Kevin Bednar

>repairing.

I think you'll find that the main thing the "no-radial" verticals have going for them is just that -- no radials. In my experience, a traditional 1/4 wave -- possibly top-loaded -- vertical with ground radials will out-perform any of the "no-radial" variations by a significant margin.

MFJ makes both types. I'm currently trying out one of the 1/4 wave models for 80 and 40 and it works great (it's top-loaded on 80). I do have fifty 1/4 wavelength radials under it, and will add about twenty-five more as time allows. I'm considering building an array of four of these.

FWIW, I'm generally not a fan of MFJ equipment, but they've impressed me with this simple but well-constructed design as well as with their MFJ-259 antenna analyzer, which is probably the single most useful piece of equipment I've added to my collection in years.

1641. Re: 8877 war stories? ur input

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-30 00:00:00 UTC
From: James Garland <garland@ohstpy.mps.ohio-state.edu>
Message-ID: <4m5f8h$541@pacific.mps.ohio-state.edu>
Source record: 201862

I have used 8877s since the early 1970s, and have built several amplifiers using them. Some of the early 8877s (1970s vintage) had production problems, and I had one develop an open filament. Mostly, however, 8877s are extremely rugged and long-lived, provided that they are used within their ratings. Some observations:

1. Don't exceed either the 4KV plate voltage (actually 4400V should be okay, but don't go any higher) rating or the 1.0 Amp plate current rating. The tubes will produce extraordinary amounts of power if pushed, but life expectancy will be greatly reduced. I remember EIMAC's Bob Sutherland W6PO telling me once of an EIMAC life test in which EIMAC engineers ran a single 8877 at 5KV and 2A plate current (10,000 Watts!) for several hours before it failed. (As I recall, they used a huge blower to carry off the heat.) The cathode surface area can't support more than 1.0 Amps emission without damage.

2. A grid current trip circuit is essential. If the grid is overheated, the gold plating will evaporate off the grid, shorting the tube life expectancy to several hundred hours. You won't notice any immediate problem, but the tube will be ruined.

3. Adhere to the specificed 4.75-5.25V filament voltage carefully. Many hams run the filament at the low end of the range in the belief that the tube life expectancy will be increased. I lost a tube by setting the voltage a 4.8V, without allowing for normal variations in the line voltage in my shack. Over time, I ran the filament too cool and ruined the tube. I'd stick to 5.0V to be on the safe side.

4. Don't use the fiberglass chimney (no longer sold, but still available at hamfests). You'll eventually have arcing problems between the anode and the chimney retaining clips. Better to spring for the teflon chimney.

5. I don't recommend the use of filament chokes, unless you want to drop the filament voltage a tenth of a volt or so (see point 3). I've done careful efficiency tests both with and without chokes and could see no difference. I also don't think filament inrush current limiters are necessary for the tube, though they seem to be in vogue these days.

6. Use good plate circuit design practice. I recommend a Radio Switch model 86 shorting switch for the bandswitch. A non-shorting switch can be used if absolutely necessary, but I'd recommend a larger switch (e.g. the model 88) to minimize arcing problems. Use of a non-shorting switch can lead to very high voltages induced on the unused inductances in the tank circuit (e.g., arcing of the 80 meter coil when operating on 10 meters) because of autotransformer effects. Also, take care to use good parasitic suprressors, preferably in the cathode circuit as well as the plate

circuit.

7. Make sure you let the tube warm up adequately before drawing plate current. The time delay on my amplifiers is set at five minutes.

73,

Jim W8ZR

Hello to all. Our club has recently come into the possesion of a new Radio Shack HTX-242 2 meter mobile radio. Our hopes are to use this radio as a remote base in conjunction with our DRC186 repeater controller. Side by side, the HTX-242 and the Kenwood TM-241A appear nearly identical. The Kenwood utilizes an 8 pin DIN type mike connector and the Radio Shack uses an 8 conductor modular plug (RJ-45). The pin-out for the HTX-242 is as follows:

1-Tone
2-Ground
3-Clock (CPU)
4-Control
5-Mic
6-PTT
7-5 VDC (500mA max)
8-Data (CPU)

Can anyone provide me with the pin-out for the Kenwood TM-241A radio. If anyone has already done the experimenting with this radio and a Doug Hall RBI-1 interface, please let me know how it went.

Thanks...Paul

I wouldn't even attempt it. The computer program is stored in
volatile RAM so you would have to keep voltage on the RAM at
all times, a very tricky thing to do while changing batteries.
I sent mine to Icom, they changed the battery and reloaded the
latest program.

>but life expectancy will be greatly reduced.

Life expectancy is mostly a matter of heater time. In amateur type duty
cycles, life shortening by exceeding CCS cathode emission ratings would
never be noticable.

>to carry off the heat.) The cathode surface area can't support more than
>1.0 Amps emission without damage.

Oxide cathodes aren't like fuses, life decrease is a gradual process over
time. It's often perfectly acceptable to run up to twice the CCS cathode
current in amateur IVS service. The cathode in the 8877 can support nearly
14 amps of emission current without damage if the duty cycle is low. The
same cathode is used in the 3CPX1500 at 50 amps of cathode current, Eimac
just runs the cathode hotter!

But the best rule is to stay at the ratings unless you understand and
accept any potential problems.

The real killer of emission is time and Gold migration caused by excessive
grid temperature. The oxide "evaporates" at nearly the same rate with zero
plate current or several amperes.

>problem, but the tube will be ruined.

Absolutely correct, and fuses aren't nearly fast enough! Always use a
fast electronic grid trip circuit.

I've also seen 8877's come back bad in amplifiers with AG6K modifications
that lower filament voltage. Running the low limit of voltage is just as
dangerous as running the high limit for life, mainly because of cathode

poisioning. Like Jim says, stay at 5 volts.

>6. Use good plate circuit design practice. I recommend a Radio Switch

>circuit.

The switch is sound advice, but I've yet to see an 8877 that was unstable even without any suppressors. This has to be one of the best and most stable tubes ever manufactured. My advice would be to ground the grid through finger stock to the chassis. The feedback capacitance is so low and self neutralizing frequency so high the tube will be unconditionally stable without any external suppression.

>7. Make sure you let the tube warm up adequately before drawing plate
>current. The time delay on my amplifiers is set at five minutes.

The real killer (other than manufacturing defects) is excessive grid current. It boils gold off the grid, and some settles on the cathode. The gold is there to passivate the tungsten grid, and it has the same effect on the cathode. It bonds with the oxide and reduces emission, forcing the operator to use more grid dissipation for the same output and starting a destructive cycle.

The oxide also fails from sublimation, it simply "boils off" the cathode from heat. The oxide "wears away" (even with no plate current) whenever the heater is on.

That last statement is exactly right. My FT-101EE had everything except the RF processor and optional CW filter. Even the fan was factory installed. I eventually added the Yaesu filter, and in '88 or '89 I installed the last RF processor that Yaesu had in stock in California.

If not for the amount of time I spend on CW, I would probably still have that rig. I've never used a more effective transmitter on SSB.

> KE4ZQV

I don't see the problem here. If the user doesn't have access to
rec.radio.swap, and he can't convince his provider to get it, then let him
do without. Is that such a hard thing to understand? Who told him that he
would be guaranteed access to a group to sell his equipment? Let THAT
person provide the group for him.

The real question is, why won't his provider carry the group? There are
certainly many other groups more objectionable than that one.

You only have 16000? I have some 19430 at last check.

Actually it can be done if you are very careful. It requires that you parallel the batteries with those tiny leads with the hooks on the end. Then you unsolder the old battery, hook it back up across the new battery, then remove and solder in the new battery. One slip and your goose is cooked. I agree with Cecil. Much better to send it to Icom.

I have seen in the ARRL Handbook, a construction project to tripple a 2 meter signal onto the 440 band. It uses 5 diodes (Step Recovery or Snap Diodes) to clip and create the third harmonic. You can drive it with an ht, and still get 2 watts or so out on the 440 band. The only drawback is that it will work well with non-linear signals, such as CW and FM - where the modulation is not carried in amplitude. If this is not a problem, take a look.

Also, your rig may be fixed onto 5 kHz freq steps, making exact 440 freqs hard to do. I no not know how tight your freq requirements are on 440.

Best of luck,

NW2M

The Raymond Sarrio Company's Ham Radio WWW site is proud to announce a FREE Ham Radio classified advertising page at http://www.csz.com/sarrio.html.

This new classified section will allow Hams to search for equipement with the help of a search engine--no need to scroll through 100's of listing before you find that special piece of gear. Plus, when you find the gear your interested in, each listing comes with point-and-click e-mail access, direct to the Ham that listed the item.

For those Hams with gear to sell, take note! It is absolutely FREE to list your equipment within Ham Classifieds, and there will be no posting time delays. Your posting will go on-line, in our classified search engine, immediately. All you need do is fill out a simple forms page, and upon its (point-and-click) submission, your "For Sale" advertisement is on-line within 1 hour. I will be purging the classified listing initially about once every month, but that timeline will shorten as our classified numbers go up. Give it a try, and let me know how you like it. 73's Ray

It's very small and it offers 160m-2m all mode. Nothing else does.
Those are the major good points. The bad points are primarily that
the receiver is subject to overload on HF if you aren't adept at
using the attenuator at appropriate times (though that's less of
a problem when using a mobile antenna), and the wideband VHF
receive sensitivity is horrible until you modify it (the mod
isn't hard to do).

It is a good radio, and easy to operate, and very easy to mount
in a mobile. It is not a great radio, but then nothing else in
its size class is either. The Alinco DX-70 has a better HF receiver,
but won't do 2m and is only 10 watts on 6m. The Yaesu FT900 has
a better HF receiver yet, and an internal auto tuner, but it is
quite a bit larger and doesn't have 6m or 2m. The Kenwood is not
in the same class at all, and can be ignored.

Subjectively, I like mine and plan to keep it. It has enough
features and options to keep you amused for quite a while, and
there's quite a bit of potential hidden in it that can be found
through judicious modifications. It isn't my primary station radio,
however. That position still belongs to my old faithful IC-735.
(And even that radio has been surpassed by the newer top of the
line radios by all three major manufacturers.) But the IC-706
makes a dandy mobile rig in today's tight autos.

>The important thing to keep in mind is that if the interference is
>truly being caused by intermods more filtering is generally not a fix.

Good explanation, but intermod isn't limited to just in-band signals.
The usual culprits that hound us at VHF are pager transmitters operating
in the 150-160 MHz range. Thanks to poor (or non-existant) preselector
filtering in the receiver, these too can mix to produce in-band products
in the same manner as your example above. In this case, a good bandpass
filter in front of the receiver will help.

>Sorry for the length of this follow-up, but I wanted to be thorough.
>I will leave it to others to give a good explantion of receiver
>overload. My understanding is that it is due to a very strong signal
>overcoming the filtering in the receiver and showing up in the output.

That's called "blow-by".

Overload is when some stage is driven off its normal operating
point by strong signals. It normally occurs in the first RF
stage, but can happen in the mixer, post-mixer amplifier, or
even in the IF (though that would be unusual except if the
offending signal is on channel, thanks to the IF filter early
in the IF chain). When the first RF stage is driven off its
operating point, it can becomes a mixer, and so intermod can
accompany overload in a similar manner to what you describe
above, or other nasty products can be generated that find
their way into the rest of the receiver, IE overload can cause
a RF stage to generate "spatter", in much the same way an
overdriven linear amplifier at the transmitter can generate
"spatter". A high standing bias current is the primary
defense against this problem, often as much as 100 mA would
be used with a bipolar CATV trunk amplifier transistor, but
that eats batteries and isn't done in HTs. Negative feedback
can be employed as well, the Norton "noiseless" feedback circuit
is commonly used.

>hanging out there for all to see.

This is not a moderated group, but it does have a charter and there is a FAQ for the Personal Radio newsgroups. Both say that this is a *discussion* list for talking about amateur equipment, equipment problems, equipment designs (including mods), etc. They specifically tell you that this is not a for sale group. The correct group for for sale postings is rec.radio.swap.

It is unfortunate that people do not read the charter or the FAQ for newsgroups before blindly posting inappropriate material. Such is life with the likes of AOL throwing newbies onto the net without even so much as a pointer to the group charter or the FAQ. Thus we periodically have to bring the group back on course by postings such as this. There's a reason why for sale items aren't allowed in this group, but I'll let you read the FAQ to find out what it is.

As your momma should have told you, just because you see others sticking their heads in the oven isn't a good reason for you to do it too.

Most of the major two-way equipment manufacturers make these radios.
Motorola, GE/Ericsson, Tait, Maxon, etc all make GMRS models. Look
in your phone book under Two Way Radio dealers.

>
>What would be a good rig for getting started in satellite QSOs. I have
>been partial to Kenwood in my HF rigs, but would like to hear about all
>rigs that you mightrecommend. Thanks

The most widely used single radio for amateur satellite operation is
the Yaesu FT736R according to an AMSAT survey. This is a very good
radio which works the way you need a satellite radio to work. It is not
perfect (nothing is) but it is better than the boxes from the other
manufacturers all things considered. It is particularly better than
the Kenwood TS790A which I strongly urge you not to buy for satellite
operating (though aside from its thermal problems this radio is OK
for terrestrial use). The Icom IC970 is an excellent radio, but too
pricy for most of us. The IC820H is more competitive, but some of its
features aren't ideally suited for satellite operation.

The other good option, and in several ways a technically superior one,
is a pair of Icom Twins. The IC275H and IC475H make a wonderful mode B,
J, and pacsat station, with or without the satellite interface box sold
by Icom. The Kenwood TS711 and TS811 are not a good choice, too much
phase noise. Computer control is more challenging for the separates,
however, and the pair generally will cost more than an all in one box.

Finally, if you have a good HF rig suitable for driving transverters,
a good transverter is an option for one of the radios. But unless
your HF rig can operate duplex and handle two transverters at once,
it will be less useful than using one of the all in one radios intended
for satellite operation. You need to be able to monitor your downlink
while you are transmitting. This setup could substitute for one of
the separate radios, however. For mode B use, substituting a HF radio
with a good 2m receiving converter for the IC275H would be a good
plan because you can take advantage of the good filters in the HF
rig. But this would lock you out of mode J operation.

>dependent.

Perhaps better still is to have a PA with sufficient headroom and
negative feedback that it can deal with a range of drive powers
without resorting to ALC. This is where the common cathode tetrode
amp can shine. If you want to do compression, let a dedicated
speech processor in the exciter do that.

> Anyway, this firebottle and lightning voltage stuff is getting a bit
>passe, I think playing with bits of processed sand is a more deserving
>challenge. (Dons suit of armour, welding mask and gloves, digs foxhole
>and ducks)

I'd agree except the costs are still too high. RF power transistors
still run about $1 per watt while power tubes can be had for under
$0.20 per watt. The rest of the two types of amplifier may cost
roughly equivalent amounts, but the higher price for the transistors
is the killer.

Hello OM es YL�s !
Lately I was forced to reset my ts50, because the processor was nuts.
After that everything was fine except one thing:
When i switch to memory mode with the "M/V" butten, the Display shows "CH 00" or similar. I was used to see the frequency in big numbers and the memory channel number in small numbers in the display. Everything works ok, i can store frequencies in the memory and use the different security features (overwriteing memory channels) but do not get the Display the way it was. Can somebody help me ???
Tnx in advance!

>complaint of low TX audio.

Interesting. We have two of them, too, and the comments we've received have been consistent re. low TX audio. I will admit, however, that I've never actually had them on a dev scope to measure the deviation. The review I read also mentioned the low TX audio, but I'll be darned if I can find it.

>What kind of working distance do you like? I've always close talked
>palm mikes, but always to the side (across the face, not into it).

I close-talk directly into the mic with my lips touching the front and my wife also talks directly into it, but from about a quarter-inch away.

Our club repeater has one of those automatic deviation-read-back functions and I typically get a reading back from it of about 3-1/2 KHz, occasionally 4. My wife is fortunate to get it up to 3 (again, on the repeater read-back).

Perhaps it's time to get the service manual and find the deviation control. :(

Thanks for your comments!

I'm considering the Yaesu FT-8500 dual-band mobile, since it's the only unit with 70cm capability and alphanumerics. I am looking at the radio with the more normal MH-39 microphone. In fact, HRO in Burbank said you can even get the FS-10 mic anymore!

What are people's impressions of this unit? Any rumors about the next model (an FT-9000?). Hopefully more characters (>6) for the alphanumeric display?

> >Jack WB3U
> No, there weren't. I had forgotten about the EX model which is the one
> without 160m and the upper 10m segments.

In regards to 101's, there were many variations of each of the same series... I have a EX with all the 10 - 160 an 11 meters on the band switch. The changes were never ending, some not even documented; such as 40Uf 450VDC cap attached to the driver tube - behind the plate an trimmers... Even my service manual didn't show it on the schem., later service manuals may <?>

The original concept was:

101E - "Full Dress unit", everything but the optional filter; fan, speech processor, all xtals & 12VDC power supply on back.

101EE - "Little less eqpt." no fan, no processor & some no 160 x-tal installed. <no not all were exactly alike>

101EX - The stripped down unit - no 12VDC unit, no processor, no fan & no 160 x-tal. <here again this was not always true>

Each version came thru with various changes in the plug in circuit boards... Most changes are noted in the regulator board & the noise blanker board... Some radios had internally adjustable N.B., some didn't. Some rigs had a externally adj-ustable speech processor <Lever behind the Clarifier>, some didn't. Nothing consistant, everything subject to change... This was the "BEST" CB ever made; if you think it was an accident that it came with the 11 meter xtal: ""WRONG"". This unit was designed to "Sell", just like the Silytronics 1011 series radio made by the Swan company, under a different name naturally. How many rigs at that time had AM & 11 meters in it at the current design level..?

The 2 most popular mods are:

1: How to put the Am filter in an make it work right, an for the Hams' How to take it out an just put in the CW filter.

2: How to get more power out of it: Change tubes to 8950's
an jack up the plate voltage... <probably the simplest conversion
I've done...>

There were tons of other mods put out by the Fox Tango group.
There are probably more of them on 11 meters today than are
on the ham bands...

For more info contact me via e-mail
De Tom.

>>good or bad? I guess reliability is the question. The amp has a
>>grid trip circuit. My second choice is an 3cx1200A7 or 3cx1200D7
>> Any comments appreciated. 73 Lynn

Lynn,

In the mid to late 80's Eimac had a lot of trouble with 8877's. They have been pretty reliable lately. I'd stay away from tubes code dated in the 80's or early 90's.

You can find the date code number stamped on the tube, it'll be four digits like 8048 for the 48th week of 1980, or 8913 for the 13th week of 89. The serial number also gives the time of production, but the date code is easier to remember.

The problem was grid cathode shorts from bad materials, but that's pretty well disappeared..

Source record: 201948

Dan,

There are a lot of "good" antennas out there. However, you will NEVER go wrong with a Larsen antenna. They are built to commercial specs, and will last nearly forever. Fooling around with anything less will be a waste of your money. In a world of "good" antennas, Larsen makes "great" antennas.

I am not a big fan of mag mounts for many reasons, such as:
a) They have a tendency to scratch your car's paint.
b) They promote rust (moisture collects under the magnet).
c) They are easily knocked off the car by low-hanging tree branches, drive-through overhangs, etc.
d) They are tempting for young vandals to steal.
e) The coax cable is in the way coming in windows or doors, and it is easily damaged (and often hard to replace).

Consider buying a Larsen NMO mount (requires a 3/4" hole) and mounting it on the roof or rear deck of your car. I mounted a Larsen NMO mount on the cowl of my Ford pickup, on the driver's side, and routed the coax down through the firewall using some rubber grommets to protect the cable jacket where it passes through the metal. There is always some distortion to the antenna's radiation pattern when you mount it this way, but it has never kept me from yakking on the local repeater or from participating in Skywarn activities.

Flame me privately, folks, if you have a difference of opinion, don't waste newsgroup space.

Source record: 201950

Nick,

You mention only two tubes and I suspect that you are looking at the rectifier and audio output because they are glass and you can see them light up! You should also have a number of metal tubes. They are painted black and about 2/3 the height of the glass units. To see if the filament in one of them is burned out, turn the radio on for about 15 minutes, then turn it off, unplug it, and feel the metal tubes to see if they have warmed. If you find a "cold one", it is likely the bad one and you will have to either find an old time radio "ham" or repairman, or a surplus store like Fair Radio in Lima Ohio to get a replacement. If you can find an old "Ham" locally, he will probably be glad to help you get your radio working again. The S-40B was a fairly decent receiver in the 1950's and with a little attention should be repairable at little cost.

Source record: 201953

Hi all,

I have been building the Radio/Computer Control Interface featured in the July 1992 QST but have been having some problems. This is the Non-powered (external that is) 4 Transister, 2 diode design. It seems to allow software to talk to the radio so I can set modes, freq, etc....but its deaf as the day is long. I can not query the radio for frequency, mode or anything.

I was wondering if anyone had experience with this design, and if so if you have had the same problem. Or, if anyone has any ideas as to what the problem is. I would appreciate any e-mail anyone can send me regarding this.

As soon as I can get the inteface working, I can test out my windows software I wrote to control the IC-706. Right now, as I said earlier, the setting of the radio works fine, but getting info from the radio just doesn't work. I've even tested this with other canned software packages and have had the same result.

Comments about degrading IMD of many TX'x at reduced power (that I've also seen) deleted

: Plus ALC
: overshoot becomes a problem.

This is classic! and the behaviour on speech with typical syllabic rates can be disgusting.

The gain controlled amplifiers are usually operated in a region approximating to linear dB's per volt, while the detectors are in an approximately linear volts in to volts out region. The net result is level dependent loop gain; giving loop response that depends on the chosen power level.

With a PA following an exciter, if the PA gain is enough to ensure that it compresses before the exciter (on all bands) then it makes sense to move the dominant ALC detector to the output of the PA, and to scale the detector output to set the loop gain to about what it was in the exciter when operated barefoot at it's prime design power - 100W.

Better still would be to have a logarithmic power detector like an AD640 and redesign the ALC loop for a decent response that is not level dependent.

The ALC transient response can be fixed, the transmit IMD/splatter is best fixed by designing a *good* exciter from scratch.

While a tolerable power amplifier can be designed around either triodes or tetrodes, I think the grounded grid triodes have the edge with a number of modest advantages - simpler circuitry and power supplies, simpler protection, simpler decoupling, robust stability, and compatibility with optimum exciter operation. On VHF/UHF where exciter power is normally lower, I think I'd go the tetrode route to avoid having to add two stages of power amplification.

Anyway, this firebottle and lightning voltage stuff is getting a bit passe, I think playing with bits of processed sand is a more deserving challenge. (Dons suit of armour, welding mask and gloves, digs foxhole and ducks)

Cheers
David

1707. STILL WANTED: OLD K-40 MICROPHONE

Newsgroup: rec.radio.amateur.equipment
Date: 1996-04-30 00:00:00 UTC
From: padawer@usit.net
Message-ID: <padawer-3004960940590001@padawer.ppp.usit.net>

I'm still looking for one of the speech processor microphones offered by K-40 (American Antenna, Inc.) for so many years. If anyone has a working model in a junkbox somewhere, I'd very much appreciate an email. (I do realize this was a product marketed mostly toward the CB market, so please no flames <g>. I do have a use for the old pup.)

Thanks!

I think you'll find that they're not out to keep your money with nothing
in return. They are, however, extremely slow, as I received my order
yesterday (4/29) which was placed on 2/1/96. On the other hand, they
didn't deposit my check until shipment was made. The quality is
excellent and they're dirt cheap compared to others. Just don't order
from them if you need your xtals in a hurry! hi hi

Not sure of that, they still advertise both. I recently bought the FT-8500 with the MH-39 mike.

> What are people's impressions of this unit? Any rumors about the next
> model (an FT-9000?). Hopefully more characters (>6) for the alphanumeric
> display?

Six is all.

I like mine, but it did have a problem with a slight high frequency background noise on its audio. This was solved by putting a 220 uF 16V cap across the speaker leads, according to a Yaesu tech bulletin. Several other FT-8500 owners said they had the same noise, mainly noticeable when earphones are used. Yaesu tech support people think it is internally generated from a PLL circuit.

The radio does not come with the remote mount kit, so if you plan to use the removeable faceplate, you'll have to buy it.

All reports on my signal and output quality are positive. Several hams have asked what kind of rig I'm using - remarking that it sounds exceptional. The unit is very compact and solid. The case is nicely finished. Display is very easly to read. I like the way it flashes the frequency which is being received, so that if you monitor both bands, a quick glance tells you which one is active.

Operating it with a Cushcraft AR-270 on my chimney, I can hit repeaters all over the metro Dallas area with 10W very solid and easily. No sign of intermod problems yet, but I have not taken it into the downtown area yet.

It has a miniature multi-speed fan, thermostatically controlled (I think) integrated into the heat sink at the rear of the unit. It is fairly quiet, but I wonder about the long range reliability of the fan - no indication of problems yet.

My only complaint about the rig is that the power leads - about a foot long - come through the back of the unit to a modular connector (wires directly soldered to pads on the board) rather than having a jack on the radio.

The only controls on the radio itself are via one small knob which switches power and can change band and frequency. All other functions must be accessed via the buttons on the mike. It has a fairly complex menu system to get to some of the control functions like sub-band operation, but after a few days the operation of most functions is not too difficult.

I like the feel of the MH-39 mike, and when used with a remote speaker the audio out of the rig is good and reasonably strong.

Take all this with a grain of salt as I'm a rookie and have not operated any other mobile rigs more than a few minutes. I can compare only to my HT, and it of course gets out much better.

Hi David,

I certainly agree with you.

Grounded grid triodes **clearly** have the advantage in HF (and even VHF) amplifiers when gains of under 15 dB and circuit and operating simplicity is required. There is absolutely no doubt of that fact. That's the real reason hi-mu triodes took over the amateur PA market.

The simplicity and advantages of tetrodes has been greatly overrated, I suspect solely for marketing reasons. The most vocal supporters of incorrect "tetrode advantages" are obviously totally unfamiliar with design, operation, and measurement of power amplifiers, but they plod ahead and mis-stated simple technical facts.

We all have to live up or down the band from people "throttling back" 100 watt (or more) exciters to drive tubes that are fussier to tune and operate.

With tetrodes... tuning becomes more critical, the circuit more sensitive to layout, voltage stability and dynamic regulation of the screen becomes a very important issue, the grids need protection for mistuning and improper operation as well as supply failures, and the operator has to be more careful when adjusting drive power.

To top off all those disadvantages, now the rig is expected to preform nicely at reduced power, perhaps ten or twenty percent of the original design value. Even ignoring increased IMD that frequently occurs when exciters are operated at greatly reduced power, most exciters (if not all) suffer severe ALC overshoot and slow transient response in the power control circuits.

I've measured a Kenwood TS-950 with a few cycles of RF output over 250 watts peak at the start of each new phrase on SSB while the power control was set at 50 watts. Imagine the leading edge voice splatter from a rig like that cut back to 20 or 30 watts to drive an improperly swamped tetrode grid!

Not only will exciters produce a bit more garbage (as a general rule) driving mis-designed tetrodes, tetrode amplifiers themselves tend to be less sanitary without the most careful attention to tuning and circuit design.

I've yet to see any response accurately disputing these simple technical truths.

If only it were that simple. The fact is that there are more than a few news systems out there that, due to policy reasons, do not accept the .swap group. A very common reason is that they cannot accept postings that benefit a particular individual; this is the norm at sites run by the US military. It's only a matter of time before those sites will be forced to drop this group as well, if the forsale ads continue. It's already happened at one site that I know of. You're not going to be able to change those sites' policies, so don't even bother flaming them; their users are simply out of luck.

The charter of this group excludes forsale postings for a very good reason. Please follow it.

>dynamics.

Gary, these numbers are seriously flawed. The fact that you arrived at a necessary peak SPL of 152 dB for music should have told you that immediately. If a typical speaker has a rated sensitivity of 90 dB SPL at 1 watt/1 meter, then 152 dB at 1 meter would require approximately 1.7 million watts!

Let me give you some accurate (although approximate) numbers from my references that should help put this in perspective:

Threshold of Hearing: 0 dB
A Quiet Room: 35 dB
A Busy Street: 70 dB
Thunder: 110 dB
75 Piece Orchestra at 15': 115 dB
Threshold of Feeling: 120 dB
Threshold of Pain: 140 dB
Jet Engine at Close Proximity: 155 dB
12' Cannon at Muzzle: 220 dB

For purposes of a musical reference, the orchestra mentioned above will produce its greatest peak-to-average SPL ratio in the area of 200-400 Hz, and that ratio will be approximately 20 dB.

In addition, the total dynamic range of the orchestra (from pianissimo to fortissimo) will be approximately 80-85 dB.

>Now a comfortable listening level is 80 dba, and that centers
>you in the usable range. If it takes 40 watts to maintain that
>sound level, a dynamic transient only 13 db greater, IE 93 dba,
>will require an amp with a 800 watt peak output to avoid
>clipping distortion.

Let's apply the *real* numbers to this. If the listener is *2 meters* from the speaker described above, 80 dB average SPL will be produced by an average drive power (approximate) of 0.4 watt. Under these conditions, the peak SPL of the orchestra will be 20 dB greater, or 100 dB SPL. This will require approximately 40 watts, not the 800 watts previously claimed.

This example doesn't produce the actual peak SPL that exists at a distance of 15' from a live performance, but it does satisfy the description of filling the room and creating a comfortable listening level of 80 dB average SPL. Actually, the power necessary to extract 115 dB SPL from this speaker would be approximately 1,300 watts, which is why very few systems can reproduce that level. Remember, too, that the Threshold of Feeling is only 5 dB above this, and that these levels can cause permanent hearing damage over an extended period.

>>Also, which speakers are "most people" using that are capable
>>of reproducing the 800 watts peak that you claim is necessary?

>Many speakers are capable of handling a 800 watt transient
>excursion. This isn't sinewave power you realize, it is a
>transient.

Yes, but I have significant reservations about the claim that "many" speakers can do this. I think the speakers that can are greatly outnumbered by those that can't.

>The IHF has a rating scale for this. My little
>Polk Compact reference speakers have an IHF rating of 480
>watts, which won't do the job, but then they don't need
>40 watts to generate a 80 dba SPL either. Their bigger
>brothers, the reference series, has an IHF rating of 1600
>watts and will serve nicely.

Because we now know that 800 watts isn't necessary, I'm not sure how relevant the IHF ratings are at this point. I also don't remember what frequency(s) that IHF tests are conducted at and I don't know the size of the drivers in the Polk speakers. Nevertheless, I think it would be worthwhile to provide a representative example of the process involved in determining the typical limits of cone excursion. This is only intended to provide a point of reference regarding the relative capabilities of acoustic suspension speakers in general.

A typical 15" woofer will exhibit a peak cone excursion of approximately 0.23" when delivering 1 *acoustic* watt at 50 Hz. If we assume this woofer is rated to produce 90 dB SPL at 1 watt/1 meter at this frequency, calculations involving SPL, actual sound pressure and sound power show that this speaker has an efficiency of approximately 0.56%. Therefore, to deliver 1 acoustic watt, we will need to apply 179 electrical watts.

Because we now know that 179 watts will create a cone excursion 0.23", we also know that 358 watts will create an excursion of 0.46" and that 716 watts will create an excursion of 0.92". The practical limit to cone excursion will probably lie somewhere in the vicinity of 0.5"-0.7" if our theoretical model is a high compliance woofer in a sealed enclosure. Therefore, I would guess that it will probably "clip" at about 400 watts.

If we now assume that this is a medium-duty woofer with a continuous power rating of 100 watts RMS, it can be seen that the peak-to-average power capability is about 4:1 when operated at its continuous (average) power rating with a sine wave. However, in music, the average power will normally be much less than 100 watts at the point where peaks approach this speaker's limit. Using the example of the orchestra again, peaks at 400 watts would indicate a maximum average power that is 20 dB below that, or 4 watts.

At this point, it is worth recalling the previous example based on an average listening level of 80 dB SPL. Those results indicated that no more than 40 watts peak capability would be necessary, which places the cabilities of this speaker well within the required range. That example, together with the above excursion calculations, strongly supports the contention that most speakers are not only unable to handle monstrous amounts of peak power (like 800 watts), but also that there is little reason for them to do so.

As a final note on this, the 0.56% efficiency calculated for the theoretical speaker is typical for acoustic suspension systems. Nearly all of these are below 1%. Ported (bass reflex) systems usually fall between 3% and 4%. I don't know the efficiency of the woofer horn in a Klipsch, but at something like 105 dB SPL at 1 watt/1 meter, 10 watts will create the 75 piece orchestra at live levels from fifteen feet away. Not that anyone would wnat to do that, of course. ;)

>I don't fully understand it.

Tubes do clip differently than transistors, and the distortion produced much more to do with non-linearity in the tube than actually reaching the supply voltage or current saturation. The problem in tubes occurs gradually, because the current demand moves into a non-linear part of the grid voltage to plate current curves. This always occurs long before a current emission problem, although voltage swing clipping can occur if the plate's load impedance is too high.

>should have tried a low pass filter.

Right on target again Jack. The low pass filter action is pointless. Most well designed high fidelity audio transformers go well about the limit of the human ear. Any "rounding off" by a low pass filter or transformer would be would inaudible to humans.

As per speaker damping provided by the amplifier, I'm puzzled by some of the comments. But that isn't anything I've ever thought about or researched, so I'll hold my tounge.

Distortion products are another story. The "in-band" IMD distortion makes the observable difference, not the ultrasonic stuff. No way will a simple low pass or audio transformer will make a transistor amp have the same distortion characteristics as a tube amp.

I also noticed the low audio with the external microphone for the HTX-202.

From a review of the schematic it is clear there are ways of correcting this by opening the radio. However I did run across a novel approach which does not require opening the radio itself with all of it's inherent risks.

The following information regarding low audio with the HTX-202 was found at:

http://pages.prodigy.com/CA/LA/htx202htx404/htx202htx404.html

Title : Low ext mic audio on the HTX-202 and HTX-404

If you own the HTX radio you probably already know about the low external audio problem. I have tried a few different brand mic's and they all failed to get any significant audio into the radio. There is a good reason for this. The problem is the radio does not provide enough voltage to properly bias an ext condenser mic. When the radio is keyed the voltage at the ext condenser mic drops to about 2 tenths of a volt. Most common condenser mic's need a minimum of 2 volts and a nominal of about 4.5 volts. Design flaw or design feature. You be the judge. There is an easy way to get around this. I will tell you how to modify the Radio Shack speaker mic to get very respectable audio out of it. You then will be able to amaze all the smug Yaesu and Icom owners that have looked down at your HTX rig.

You will need the following parts from your friendly neighborhood Radio Shack

cat num,..... description,..... generic

19-310..... speaker mic

270-430..... lithium batt holder.... 20 mm single cell

23-162..... lithium battery..... dl2032..3v 180mah

270-092..... condenser mic..... -65 db sens 2v-10v

.33 microfarad cap,disc type or any small profile type cap

At this point I should say that this is a " use at your own risk" modification. It is not approved by the manufacturer and if they knew it would probably void your warranty. Any damage to your radio because of an incorrectly implemented mod to the speaker mike is solely your responsibility. Now having said that, probably the only thing to happen if you blow the mic mod is that the mic won't work or you won't be able to key the radio from the external ptt switch. They made the radio hard to hurt through the ext mike jack.

#1: Unsolder the ptt switch.

#2: Cut the leads to the mic element and remove original mic.

#3: Connect the red wire from the main cable that was going to the ptt switch before to the side of the resistor that is not connected to the speaker.

#4: Install the ptt switch in line between the resistor and ground which is the minus terminal on the speaker.

#5: Connect the .33 mf cap to the top of the resistor where the red wire is.

#6: Connect the white signal wire from the condenser mic to the other side of the .33mf cap.

#7: Connect the shield wire from the condenser mic to the ground side of the resistor. This would be above the switch but on the low side of the resistor. This is important because if this is wrong the battery will only last a few days instead of a year or more.

#8: Connect the minus side of the battery holder to the ground point that is the minus terminal on the speaker.

#9: Connect the positive terminal of the battery holder to the red bias wire that comes from the mic element.

#10: Install the battery.

#11: Check with a volt meter to check that the bias wire on the mic is getting aprox 3.1 volts positve.

That should be it. The .33mf cap keeps the radio {red wire from main cable} from seeing the ext dc from the battery. The ptt switch grounds the resistor and causes the radio to key and completes the ground for the mic element. When the radio is not keyed the battery is looking at a high impeadance instead of the 3k impeadance the mic presents when in circuit. I checked modulation on my rig by putting the HTX on a dummy load at low power and listened with headphones to a scanner. this is a good way to insure that all is well before you take to the bands. Also I should note that this type of mod can be made to other brand mic's. Before I tried the Radio Shack model I modified a MFJ-284. The same principals are involved but in the case of the MFJ there is more latitude in how you accomplish the mod. The ptt switch is dpdt on the MFJ and only spdt on the Radio Shack. Having two sets of switch contacts allows you to use one set to ground the resistor and the other set to apply the positve voltage to the mic element. Applying the positive voltage rather than grounding the mic is probably prefered. If you use the Radio Shack mic you don't have much choice and will need to use the grounding method on the mic.

Now there are better parts available to do this mod, a noise cancelling higher sensetivity mic for instance. If you are interested in really having a high performance mic send a self addressed stamped envelope and I will tell you how obtain these better performance parts. Send the envelope to:

Terrapin Sales P.O. Box 12426 La Crescenta, Ca. 91224-5426

Another cool place for HTX-202 and HTX-404 info as well as other ham related topics is at the
following address.

http://ourworld.compuserve.com:80/homepages/wa3rvt/

Make sure you check out .

The above was located at:
http://pages.prodigy.com/CA/LA/htx202htx404/htx202htx404.html

Be careful if you chose the route of internal adjustment for the external microphone audio. In so doing you will probably be in a position of over deviating with the built in microphone.

Rob:

I was fully aware of that. It wasn't the cellular reception I was concerned with. It was the FT-50R's inability to function in the WFM mode that it claimed to have, but didn't. I wanted to use it for commercial FM broadcast, and T.V. sound, which it can receive, but it sounds like garbage due to the not-wide-enough WFM mode.

It's too bad. Other than that, it is a super radio.

You're at the same point I was at 3 mo. ago. I opted for the Icom because it had an external DC jack (the 51r has none) and I planned on plugging in a variety of power sources (like my gel cel when I'm bicycle mobile). As a bonus it accepts a standard mini barrel connector as opposed to some proprietary size.

The 51r has many more convenience features (like the computer interface) than the w31a, but the Icom seems to have much better receiver section - it's less prone intermod & other airborne grunge. The extended mod opens receive to 50~920 mHz (incl. cel phn). I haven't checked the limits of the ext tx, but seems to be ~110-170, 400-480.

The only trouble with this comparison is that you don't need a power
supply with the 736 (I assume that is what the FP700 is). It is built
in the 736.

1733. IC-706 CI-V Codes

Newsgroup: rec.radio.amateur.equipment
Date: 1996-05-01 00:00:00 UTC
From: Jeffery Ramlow <n9wbr@gglbbs.com>
Message-ID: <31882B4A.1307@gglbbs.com>
Source record: 201732

I've been working on an interface program for the Icom 706 and have a few questions. There is a list of available commands in the 706 Book, and a call to Icom determined that these are the ONLY command codes available under CI-V. My question is, is this true? Are there any undocumented codes? It seems to me that the in-ability to set tone, plus a number of other really good features is somewhat limiting.

I know, Icom says..... But reality is a little more complex. I have been lead to believe that there are other codes that are undocumented in the IC-706 Manual. Such as the code to read Mode and code to read Frequency which are not in the manual. Are there more?

Any help, or general information anyone has would be greatly appreciated.

John,

IMHO, listening on a s.w. receiver is one of the best ways to learn code because you learn under 'real-world' conditions. This method, however, can take a LONG time! This is also true of code tapes. Most will start a tape, get saturated try again another day and before you know it, you've had you tapes for a month and still no license.

Instead, check in your area for a weekend crash course. These folks can get you licensed in one weekend. In fact, you walk out of the door with your temp. license in hand! Gordon West has a great course and many earn their license in his schools. Considering all you get, the price is very reasonable. Even if you had to travel to a larger city and stay over-night, you still have a valid license in one or two days. I think the no code training is one day.

If packet radio is your forte, consider a two meter radio. In most cases, a small antenna is all that is required and with a small power supply (unless you are running 50 watts), you can be on the air in no time, for a reasonable amount of money.

Consider going to a Ham Radio store and looking over the used equipment and asking a lot of questions. While you are there, be sure to check the bulletin board for good buys. If you do a little homework and find a radio you want, ask here if it has a good track record. You may want to consider a want ad here or in a larger newspaper, esp. on Sundays. If possible, ask to see the equipment in operation.
If you know a ham, many repeaters have a radio swap meet once a week or so, try there too. Radio swapmeets or flea markets can be another great source for radios and equipment. Here is a the very best advice I can offer before buying... ASK if it works, look him in the eye for his answer. Next ask if he is willing to give you his telephone number if it doesn't. If he (or she) hesitates even a moment to give you his number/verbal guarantee, walk away.

These tips can save you hunderds of dollars.

> before i spend my money can anyone give me any comments on it.

Hi Mike:

I suggest you go to DejaNews and do a search on "IC-706" and "IC706" for a dump of what is in the usenet archives on the rig. Also, Alta Vista can be used to get current articles. I read up this way to get a good idea as well as other articles I could dig up (one below was pulled off QST's posting).

I decided to buy and have had it a week now. Just this AM I tried DXing from the car on 20 meters during the commute. The thrill of working a TI (Costa Rica) on my first try was worth the effort I put into the antenna (GOOD auto installations are somewhat labor intensive). I also worked Hawaii first try last night on 20. Though I planned to use the rig more in the shack than in the car, that may now change <g>.

As far as the features, etc., read the posted articles on usenet. The only lacking is the out of band receive above 100 MHz (including broadcast FM) is poor as everyone says it'd be. I plan to do the mod that's supposed to fix this after warranty expires. As far as the good stuff, there is plenty. I love the band coverage (160 thru 2), small size, and excellent performance for the money. It is really fun to use. There are at least three other competitors from Kenwood, Yaesu and Alinco, but the consensus I gather is the IC-706 for a host of reasons.

Hope to hear you on the air!

73 de Chris

QST (March 96, I think)

It seems that radio manufacturers are all trying to outdo each
other by putting more and more features into smaller and smaller
packages. With the IC-706, ICOM has outdone all their competitors by
offering an MF/HF/VHF transceiver that covers all bands from 160- to
2-meters! The entire unit with the detachable front panel attached,
measures less than 7- X 8- X 2.5-inches (18- X 20- X 6-cm.) and weighs
only 5.5-pounds (2.75-kg.), not including power supply.

Not only that, they also have given the rig almost every operating
feature that is possessed by full-sized rigs many times larger. The
transmitter output is 100-watts from 160- through 6-meters, and 10-watts
on 2-meters. Its receiver covers from 300-KHz. to 200-MHz.,
continuously, and it operates all of the usual modes: CW, SSB, AM, NBFM,
and digital modes. It uses true FSK in digital operation. It also
receives wide-band FM and provides scanning functions. In addition, it
has a built-in keyer and 101 memories.

The little rig even contains some features that many of its big brothers and competitors do not have, such as the option of listening to CW on either sideband, VOX with independent delay settings for each mode, adjustable CW offset with tracking sidetone pitch, first-in/first-out scratch-pad memories, speech compressor with adjustable gain, and software settings to modify the SSB transmit audio response to fit one's microphone and personal choices. It also provides optional computer interfacing and band-in-use outputs to operate external linear amplifiers and for remote antenna switching. To enable the rig to handle the heat dissipation of its 100-watt transmitter, the designer made the chassis a die-cast heatsink on which the PC-boards are mounted. This also makes the rig exceptionally rugged. Power requirement at 13.8-volts is a nominal 20-amps while transmitting; it drops as low as 1.5-amps when receiving with the output squelched.

With all of those functions and operating choices, the designers had a major problem of how to provide all of the necessary controls on a front panel only 2.5- X 7-inches (6- X 18-cm.) in size. The tuning knob, alone, takes up the full height and about 2.5-inches (6-cm.) of the width, leaving only about 4.5-inches (11-cm.) of width for the LCD digital display and all other controls. Their solution to the dilemma was a clever system of menus, with function keys that access the menu choices, plus a number of multi-function buttons. In addition to the tuning knob, there are only two other pairs of concentric control knobs. One is RF/SQL that acts either as the RF gain or the squelch control; the other is RIT/Shift.

Most of the control buttons initiate at least two different actions. Pushing the button briefly gets one action; pushing and holding it for two seconds or more gets another. This scheme, plus a hierarchy of menus that are displayed on the backlighted LCD digital display, provide the flexibility to control the inherently complex functionality of the rig.

The reviewers found that, although the complexity was initially daunting, it did not take long until the control functions became essentially intuitive. The reviewer's summary states that the rig on all ham bands, up to and including 6- and 2-meters, provides all the functions and receiver sensitivity that could be expected. They did, however, criticize the transmitter's IMD. On HF, they rated its performance as acceptable, though not "stellar"; but on 6- and 2-meters, the distortion is bad enough that it may cause significant splatter, especially if used with an amplifier. As for receiving, the ARRL laboratory tests of dynamic range, IMD, and sensitivity indicate that the performance is entirely creditable, and not far below the very best of modern transceivers.

The manufacturer's list price for the IC-706 is $1560. An automatic antenna tuner for all bands except 2-meters, Model AT-180, is available for $599. Optional i.f. filters are priced at $84 to $106, depending upon bandwidth. No a.c. power supply is listed.

Hi Mike:

It's worth the money (I wish the same was true for the accessories, gees Icom)!

It's very straightforward once you get used to the menu system (experience with modern digitally controlled radios with set modes and such helps speed you along). If you can't program your VCR, forget the rig <g>! Hams should have no problems and most adapt more qucikly to the 706 than comparable rigs. I still have to go for the manual to program my Azden 2m rig and Realistic 202 HT. The memory/scanning features are the most involved to set-up, but the least likely used day to day.

I am very happy with the radio (only a week with it so far). I suggest you go to DejaNews and do a search on "IC-706" and "IC706" for a dump of what is in the usenet archives on the rig. Also, Alta Vista can be used to get current articles. I read up this way to get a good idea as well as other articles I could dig up (one below was pulled off QST's posting).

Just this AM I tried DXing from the car on 20 meters during the commute. The thrill of working a TI (Costa Rica) on my first try was worth the effort I put into the antenna (GOOD auto installations are somewhat labor intensive). I also worked Hawaii first try last night on 20. Though I planned to use the rig more in the shack than in the car, that may now change <g>.

As far as the features, etc., read the posted articles on usenet. The only lacking is the out of band receive above 100 MHz (including broadcast FM) is poor as everyone says it'd be. I plan to do the mod that's supposed to fix this after warranty expires. As far as the good stuff, there is plenty. I love the band coverage (160 thru 2), small size, and excellent performance for the money. It is really fun to use. There are at least three other competitors from Kenwood, Yaesu and Alinco, but the consensus I gather is the IC-706 for a host of reasons.

Hope to hear you on the air!

73 de Chris

QST (March 96, I think)

It seems that radio manufacturers are all trying to outdo each
other by putting more and more features into smaller and smaller
packages. With the IC-706, ICOM has outdone all their competitors by
offering an MF/HF/VHF transceiver that covers all bands from 160- to
2-meters! The entire unit with the detachable front panel attached,
measures less than 7- X 8- X 2.5-inches (18- X 20- X 6-cm.) and weighs
only 5.5-pounds (2.75-kg.), not including power supply.

Not only that, they also have given the rig almost every operating feature that is possessed by full-sized rigs many times larger. The transmitter output is 100-watts from 160- through 6-meters, and 10-watts on 2-meters. Its receiver covers from 300-KHz. to 200-MHz., continuously, and it operates all of the usual modes: CW, SSB, AM, NBFM, and digital modes. It uses true FSK in digital operation. It also receives wide-band FM and provides scanning functions. In addition, it has a built-in keyer and 101 memories.

The little rig even contains some features that many of its big brothers and competitors do not have, such as the option of listening to CW on either sideband, VOX with independent delay settings for each mode, adjustable CW offset with tracking sidetone pitch, first-in/first-out scratch-pad memories, speech compressor with adjustable gain, and software settings to modify the SSB transmit audio response to fit one's microphone and personal choices. It also provides optional computer interfacing and band-in-use outputs to operate external linear amplifiers and for remote antenna switching. To enable the rig to handle the heat dissipation of its 100-watt transmitter, the designer made the chassis a die-cast heatsink on which the PC-boards are mounted. This also makes the rig exceptionally rugged. Power requirement at 13.8-volts is a nominal 20-amps while transmitting; it drops as low as 1.5-amps when receiving with the output squelched.

With all of those functions and operating choices, the designers had a major problem of how to provide all of the necessary controls on a front panel only 2.5- X 7-inches (6- X 18-cm.) in size. The tuning knob, alone, takes up the full height and about 2.5-inches (6-cm.) of the width, leaving only about 4.5-inches (11-cm.) of width for the LCD digital display and all other controls. Their solution to the dilemma was a clever system of menus, with function keys that access the menu choices, plus a number of multi-function buttons. In addition to the tuning knob, there are only two other pairs of concentric control knobs. One is RF/SQL that acts either as the RF gain or the squelch control; the other is RIT/Shift.

Most of the control buttons initiate at least two different actions. Pushing the button briefly gets one action; pushing and holding it for two seconds or more gets another. This scheme, plus a hierarchy of menus that are displayed on the backlighted LCD digital display, provide the flexibility to control the inherently complex functionality of the rig.

The reviewers found that, although the complexity was initially daunting, it did not take long until the control functions became essentially intuitive. The reviewer's summary states that the rig on all ham bands, up to and including 6- and 2-meters, provides all the functions and receiver sensitivity that could be expected. They did, however, criticize the transmitter's IMD. On HF, they rated its performance as acceptable, though not "stellar"; but on 6- and 2-meters, the distortion is bad enough that it may cause significant splatter, especially if used with an amplifier. As for receiving, the ARRL

laboratory tests of dynamic range, IMD, and sensitivity indicate that the performance is entirely creditable, and not far below the very best of modern transceivers.

The manufacturer's list price for the IC-706 is $1560. An automatic antenna tuner for all bands except 2-meters, Model AT-180, is available for $599. Optional i.f. filters are priced at $84 to $106, depending upon bandwidth. No a.c. power supply is listed.

The report I read claimed that there was some rise time delay but not a
material shortening of the elements. Apparently both the rise and fall
edges were delayed by nearly equal amounts.

(Note: now xposted to rec.radio.equipment for greater depth of experience.)

Perhaps the manual was stating the matter too strongly. It was no doubt just suggesting that it *ought* not be used without ALC control which would prevent overdrive and distortion or even damage. Remember that ALC is an output from the amplifier and so the lack of a connection to that terminal can do nothing to prevent the amplifier from operating.

>for that in speaker enclosure design.

Gary,

There are some very significant errors in your reply regarding
the fundamental principles of speakers. I think we will need to
clear this up before the above paragraph can be fully discussed.

>Now you can apply mechanical friction damping to a speaker
>cone, using its flexible support as a friction "shock
>absorber", but that hurts speaker efficiency and limits cone
>excursion, so it is rarely used today.

This is not correct. The efficiency of short throw woofers with
accordian surrounds is considerably higher than long throw
designs. Limiting the cone excursion allows the designer to
build a magnet structure with a tighter gap and less overhang.

There are several reasons these speakers aren't often seen
today, but foremost is system cost. Stiffer suspensions
raise the frequency of resonance, which in turn renders these
speakers unsuitable for use in small, infinite baffle (acoustic
suspension) enclosures. In order to achieve reasonable low-
frequency response, the enclosure must be *very* large or
must be ported (or a variant thereof).

Even when the design is ported, the enclosure must be fairly
large by today's standards in order for the port to provide
significant acoustic reinforcement from the rear of the cone.
The smaller the enclosure, the smaller the port must be in order
to tune the enclosure volume to the driver. As the enclosure
volume is reduced, the port eventually becomes so small that it
provides no significant benefit.

The bottom line here is that it is much cheaper to mount a large,
long-throw, loosely-suspended woofer in a small cabinet and fill
the box with acoustic insulation than to build a larger enclosure
and tune it to the woofer. In fact, because no two woofers are
exactly alike, it was not uncommon in the past for manufacturers
to tune the port in each cabinet by hand after the woofer was

installed. The benefits from this can be significant, but today's market doesn't allow the cost.

None of this should be confused with the junk that has appeared on the market during the last fifteen years or so. Placing a long throw 12" woofer in a two-cubic-foot enclosure and adding a six inch port merely produces garbage.

>Or you can use an "air suspension" where the air trapped in
>the enclosure acts as a spring against the speaker cone's
>piston. There is very little friction here, so the speaker can
>be quite efficient,

Absolutely not. Placing a high compliance, long throw woofer in an infinite baffle enclosure produces the *least* efficient system. In addition to the fact that long throw drivers are less efficient, the stiffness provided by a sealed enclosure causes much of the acoustic power to be consumed in heating the internal air.

>and large cone excursions can be supported so bass response
>can be quite good, but you need some other method of damping
>the cone's resonance.

There's an implication here that a stiffly suspended cone is self-damping. That's not true at all, although the resultant increase in resonant frequency may create that impression.

>This is done by adjusting the enclosure's volume so that it is
>anti-resonant at the cone's natural resonant frequency, IE
>it will return a negative pressure wave reflection to the
>cone at the time the cone is trying to produce a positive
>pressure wave, and vice versa. This will damp the cone
>response. You can also use tuned ports, ducts, or pipes
>to achieve the same effect.

There is absolutely NO "anti-resonant" tuning in a sealed enclosure. The box is stuffed with insulation to reduce the Q and hopefully eliminate all possibility of resonance, including the type you're suggesting. As one of its other functions, the insulation also reduces reflections from internal surfaces.

Regarding your last statement, the effect of a port on speaker impedance, resonance, efficiency and damping is much different than a sealed enclosure. In a ported enclosure, the volume of trapped air does in fact resonate with the driver and the port, and these enclosures are not usually filled with insulation. Also, tuning the port is seldom sufficient in itself to achieve critical damping and secondary techniques are usually employed.

>Speakers designed to be driven by tube amps have a lot of
>mechanical damping to make up for the small electrical damping
>the tube amp offers, and speakers designed to be drive by
>transistor amps have relatively less mechanical damping to
>accomodate the larger electrical damping the transistor amp
>offers.

Tell me how designers reduce the damping of an infinite baffle speaker to suit solid-state amplifiers? Also, when they do this, which solid-state amplifier do they use for a model in order to calculate system Q? Do they use one that employs a direct-coupled output stage with 0.1 ohm emitter resistors, or one with 0.47 or 0.56 ohm resistors? What about amplifiers that have output devices in parallel, or employ a coupling cap in series with the output?

Also, when did engineers start redesigning speakers this way, and how did they compensate the other drivers for the increased woofer efficiency that results when mechanical damping is decreased?

>The audio spectrum analyzer doesn't lie, Jack. They do have
>muddy bass response when heavily damped by a solid state
>amplifier, and modern speakers sound boomy as hell when driven
>by an old tube amp. And you can see both of those defects on
>the audio spectrum analyzer as well as hear them.

Gary, I have no idea what you saw or heard. Did you conduct any tests for critical damping, or just for frequency response?

>Tubes don't clip differently from transistors when they hit the
>power supply limit (though they can also clip by hitting the
>cathode current emission limit which transistors don't have).

It's been a long time, but I seem to remember that the rounded waveform will also appear directly at the plate of the tube when the amplifier runs out of headroom. I don't want to guess about the cause of this though, and I've already stated elsewhere that I don't fully understand it.

>A low pass filter on the output of a transistor amp will
>produce the same spectrum.

Absolutely not. Manufacturers of solid state guitar amplifiers have reasearched this for years in an effort to produce an amplifier that will simulate the sound a tube amplifier produces when it clips. You won't get very far telling Fender that they should have tried a low pass filter.

>A few electrostats are good, but horns produce phase
>distortions of 10% or more, which is why big horns like the old
>Altecs aren't built anymore by anyone who cares about high
>fidelity.

Given the complexities of the market, I think a major leap of faith is required to conclude that the demise of these systems resulted from phase shift. Besides, Klipschorns are still on the market and highly prized in many circles (the only good thing to ever come out of Arkansas).

I haven't had a chance to review your numbers on SPL, but I'll comment on that in a future post.

I preformed this operation on my 735 by replacing the battery while the radio was turned on. I powered the soldering iron through a isolation transformer just to be safe. That was about 5 years ago and I need to do it again. Any other good methods for this procedure?
I thought the 745 had the program memory in ROM unlike many of the later series.

I own one of these also. SAMS has a Photofact on it (I'm holding
it in my hand). It's folder 4 of Set 122. I don't have their address
handy, but I'm sure someone else can post it. What RCA Victor tube and
GE tube are you talking about???? This unit should have 8 Tubes:

1 - 5Y3 Rectifier
1 - 6SC7 BFO/AF Amp
1 - 6K6 Power output
1 - 6H6 Detector-AVC-ANL
2 - 6SK7 1st and 2nd IF Amp
1 - 6SA7 Converter
1 - 6SG7 RF Amp

It's not really too bad of unit. I use mine for General purpose
SW listening. It shouldn't really be too hard to repair.

Take care,

Wes

1759. FT-101E FOR SALE << YAESU >>

Newsgroup: rec.radio.amateur.equipment
Date: 1996-05-02 00:00:00 UTC
From: Bill <debral@falcon.cc.ukans.edu>
Message-ID: <1996May2.000435.119048@kuhub.cc.ukans.edu>
Source record: 201746

:::::::::::::::::::: YAESU FT-101E ::::::::::::::::::::

AMATEUR TRANSCEIVER
Serial # 7L300489

STANDARD FEATURES:

* 160-10 meter AM / CW / SSB
* RF speech processor
* Noise blanker
* Owner's manual (mint)

YAESU OPTIONS INSTALLED:

* 600 Hz CW filter
* Cooling fan

DC INPUT POWER:

* 260 W - SSB
* 180 W - CW
* 80 W - AM

This transceiver is physically and electrically in absolutely
MINT condition, and meets all original Yaesu operational specifications.

No modifications!
No scratches!
No stains!
No dings!

ASKING: $450. 00

1760. KISS mode HELP !

Newsgroup: rec.radio.amateur.equipment
Date: 1996-05-02 00:00:00 UTC
From: Alex Lam <alexl@mpce.mq.edu.au>
Message-ID: <31884B26.4B04@mpce.mq.edu.au>
Source record: 201747
Cross-posted to: rec.radio.amateur.digital.misc,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

Hi all,
I am trying to have two modems talking to each other. Just then,
I have them talking with converse and transparent mode, but it didn't
working for KISS mode. In fact, they lost connection when I put them
into KISS mode.
I realise that I will no longer have AX.25 in KISS, but
I didn't expect they would lost connection !
Can anyone help ? Are there special instructions required ?

Your help will be very much appreciated. Thankyou.

Alex Lam

1761. FT-50 mods for cellular band?

Newsgroup: rec.radio.amateur.equipment
Date: 1996-05-02 00:00:00 UTC
From: 4z9chb@4x4ac.ampr.ORG
Message-ID: <64718@4x4ac.ampr.org>
Source record: 201748

Hello,

Since Yaesu says that the HT is blocked for the cellular band (869-694 MHz approx) and it can receive in the rest of the 800 MHz band, I assume that this is a software block out, and a modification of few bottons or few jumpers is needed to be done in order to receive cellular phones.

Is there anybody that might know the answer how to make it receive in the cellular band?

Any info would be great!

P.S: I saw a posting that said that you can receive cellulars on the image frequancy, but this does not satisfy me.

Tom, thanks for posting this explanation. I knew it had something
to do with the curve of the tube at various current levels, but I
couldn't quite put my finger on it.

>As per speaker damping provided by the amplifier, I'm puzzled by some
>of the comments. But that isn't anything I've ever thought about or

Let me know which comments created questions. If I've made a
mistake or haven't expained something well, I'd like to
correct it.

>No way will a simple low pass or audio transformer will make a
>transistor amp have the same distortion characteristics as a tube
>amp.

Actually, this has just reminded me that my first stereo amplifier
was a solid-state design with output transformers. It was made by
Olson and the transformers were really puny compared to genuine
hi-fi gear. Despite the shortcomings of the transformers, the
output wave at clipping was virtually dead flat compared to the
waveform from overdriven tubes.

1763. Narrow Filtering in TS-930 FSK kills KAM receive

Newsgroup: rec.radio.amateur.equipment
Date: 1996-05-02 00:00:00 UTC
From: leo@jove.com
Message-ID: <4m9bch$8vr@decius.ultra.net>
Source record: 201750

Has anyone experienced this problem:

I have installed the 2nd & 3rd IF 500Hz filters in my TS-930. When attempting to run FSK with the KAM Plus I encounter a receive problem with narrow filtering. Switching in the 500Hz filters or narrowing the VBT more than halfway using the Wide filter position causes a loss of display activity and output from the KAM. If I use an outboard DSP audio filter set to RTTY mode the KAM works properly. Only narrowing the internal IF filtering kills the KAM. I acquired the IF filters specifically for use in FSK and need to figure out what's wrong.

It's supposed to work :-)

1764. Code Practice San Francisco/Monterey Bay Areas

The distorsion is different on triode and tetrode/pentode amplifiers.
Triodes can reach high anode current when the driving grid voltage is
high enough, while tetrodes and pentodes are more limited in this
area. Therefore the triodes produce more even order harmonics while
the tetrodes and pentodes produce more odd order harmonics.

Howdy Hams - I've been lurking 'round here for awhile now and have decided it's time to bite the bullet & get involved. So a few pointers if you please.

First it seems that it would be a good idea to get a reasonable shortwave receiver and started listening. Then sign up for a license, learn that morse stuff and then get a transmitter.

Or is there a better way? And what would be a good receiver or transmitter to start with? And how much $$$$ should I expect to spend? And could I use it for packet?

Thanks in advance for helping a new guy get a clue.....

What might be going on is that the 930's filter passes frequencies other
than what the KAM is "looking" for. You may need to adjust the MARK and
SPACE parameters of the KAM to match the output passband of the radio.
Remember, of course, to keep the proper shift.

Good luck & 73

: >>effects.
True.

: >
: >Gary, this is completely untrue. Lead guitarists often run their amps
: >"wide open" in order to imitate the sound of musicians like Hendrix
: >and Stevie Ray Vaughn. The soft clipping of tubes produces an effect
: >that cannot be duplicated with either a solid-state amplifier or
: >external "fuzz" devices. Contrary to your statement, the tube
: >amplifier produces less odd-harmonic distortion when driven into
: >clipping, in turn creating a more "natural" sound.
"less odd-harmonic distortion" than high gain/high feedback designs that
clip symetrically.

: Clipping produces only odd order harmonics.
False. The symmetry of the distortion matters. Perfectly symmetrical clipping
produces only odd order harmonics. asymmetric clipping produces even
order harmonics as well. See the Guitar Effects FAQ at
http://www.eden.com/keen for some help on the musical effects of distortion.
: By definition, square
: waves are composed only of odd order harmonics in an infinite
: power series.
True, but irrelevant, as tube amps most often clip in a way that does not
produce square waves.

: The output transformer in a tube amp acts as a low
: pass filter and attenuates some of the higher order harmonics,
: hence the "rounded" appearance of tube amp clipping, but a low
: pass filter on the output of a solid state amp (Crown uses one,
: calling it an ultrasonic filter) will give you the same spectrum.
True/false. The output transformer does act as a filter, but well
designed ones have responses to well beyond the audio range. That
IS NOT that accounts for the harmonic spectrum of tube distortion.
A filter cannot put in even harmonics that were not in the original
signal without itself distorting.

: Clipping in a tube amp results when power supply voltage limits
: are reached, or when tube cathode current emission limits are
: reached.
False. In most cases it's when the forward bias of the grid is reached and the preceeding stage can't drive the grid further for impedance reasons, certainly for preamp tubes. The softer distortion occurs when the tube is run into the mushy cutoff region. Specifically is is NOT when emission limits are reached, as oxide cathodes can produce much more current than the circuit impedances generally allow them to, especially for preamp tubes.

: In a transistor amp, clipping results when power supply
: voltage limits are reached, or when power supply current limits
: are reached.
True (Hey! we found another one...)
: Unlike tubes, transistors don't exhibit a majority
: carrier current limit effect.
True but irrelevant.

: Since transistor amps typically don't use an audio output
: transformer,
False. Some do.
: they don't suffer from hystersis effects or
: saturation effects from the transformer, and the signal is
: not bandlimited by the inductance and distributed capacitance
: of the transformer windings.

: It is the presence of the iron
: core output transformer that gives the tube amp most of its
: distortion characteristics.
False. The iron core does contribute some distortion in operation, but the distortion is easily calculatable (See Radiotron Designer's Handbook for a discussion) and is not what gives "most of it's distortion characteristics". Quite a lot of the distortion characteristic comes from the fact that most tube amps use low levels of feedback. At high feedback levels, tube amps distort very much like transistor amps. At low feedback levels, the naturally softer cutoff/saturation character of the tubes shows through.

: McIntosh used a negative feedback
: winding on their output transformers to attempt to linearize
: some of these effects, but they were only partially successful.
Actually, those windings were there to lower the impedance levels (which lowers the iron distortion, see RDH) and to maximize coupling from half primary (quarter primary?) to the secondaries to allow them to get 'way into Class B without the spurious effects of cutoff ringing on the half primary that shuts down when one output turns off. I have a copy of an article by MacIntosh on this.

: Most tube amps don't even attempt to correct these distortions.

True and false. Run some distortion analysis on a MacIntosh or a well tweaked Dyna. There ain't much, and what's there is primarily low order

and less offensive than what you get from a solid stage high-feedback design.

Guitar amps do feature the distortions.

Read the source materials before editorializing, please.

HAMFEST/COMPUTERFEST CALENDAR 1996 - NORTHERN ILLINOIS
last updated April 24, 1996 |

o Please report additions or changes to Bob Parnass,
AJ9S, office phone: (708)979-5414, electronic mail: |
parnass@bell-labs.com. Thanks to Dennis Dale and ARRL
for providing some of the information.

MAY

May 5 (Sun), Sandwich, IL - DeKalb Hamfest. Sandwich Fair-
grounds, intersection of Suydam and Gletty Roads, just north
of Rt. 34. Admission $6 at gate, free parking. Talk-in on
146.73 MHz and 146.52 MHz.

May 11 (Sat) - Kankakee Area Radio Society, Peotone, IL.
Will County Fairgrounds, I-57 to exit 327 east. Admission
$5 at gate, free parking. Kids under 12 free. Info: Willis
Bowser, K9IFO, 1210 North Riverside Dr., Momence, IL 60954-
3452, tel. 815-472-2079

May 26 (Sun), Chicago, IL - Chicago ARC Hamfest. DeVry
Institute of Technology, 3300 N. Campbell. 8 AM - 3 PM,
setup at 6 AM. Admission $5 at door, free parking. Kids
under 12 free. Talk-in 147.255, 444.825. Info, call |
(312)545-3622 or (312)486-6823.

May 26 (Sun) - Computer Central, College of DuPage (see
notes at the end of this article).

JUNE

June 2 (Sun), Princeton, IL - Starved Rock RC. Bureau *
County Fairgrounds. Admission $5, free parking. Info: Deb-
bie Burton, N9DRU, 1153 Union St., Marseilles, IL 61341-
1710, tel. 815-795-2201 Usually an excellent hamfest, with
sellers from Illinois, Iowa, and Wisconsin.

June 9 (Sun), Granite City, IL - Egyptianfest '96, Egyptian | Radio Club. Granite City campus of Belleville Area College, | 1/2 mile south of I-270 on Ill Hy 203 at Maryville Road. | 8:00am to 1:00pm CDT. Annual hamfest, computer fair and | fleamarket. VE session, food and drink, indoor dealer / | exhibitor area. Talk-in 146.79 MHz. Info: Egyptian Radio | Club, P.O. box 562, Granite City, IL 62040, call Bill Dusen- | bery N9OQK at (618) 398-1456. |

June 30 (Sun), Wheaton, IL - Six Meter Club of Chicago. | DuPage County Fairgrounds. Gates open 6 AM. Admission $5 at gate. Talk-in on 146.97 MHz (107.2 PL) or 146.52 MHz. | Tickets available from Mike Corbett, K9ENZ, 606 So. Fenton | Ave, Romeoville IL 60446. 24 hour hotline for info= (708) | 442-4961. Good hamfest which moved from Santa Fe Speedway | to Wheaton this year.

Jun 30 (Sun) - Computer Central, College of DuPage (see notes at the end of this article).

JULY

Jul 13 (Sat), Oak Creek, WI - S. Milwaukee ARC Swapfest. American Legion Post 434, Shepard Ave. Admission $5. Talk-in 146.52 MHz. Info (414)762-3235.

Jul 14 (Sun), Sugar Grove, IL - Fox River Radio League. Waubonsee Community College, Rt. 47 at Harter Rd. VEC testing. Admission $5 at gate, free parking. Info: Diana WD9API, (708)293-7485. Fair, small to mid-sized hamfest.

Jul 27 (Sat), Pecatonic, IL - Rockford ARA Hamfest. Winnebago County Fairgrounds. VEC testing at 1st Baptist Church, 7th & Washington. Admission $5. Kids 10 and under free. Info, Marsha Plasters (815)399-9233 or Diana White (815)645-8545.

Jul 28 (Sun) - Computer Central, College of DuPage (see notes at the end of this article).

AUGUST

August 18 (Sun) - DuPage ARC, Stickney, IL. DuPage ARC Hamfest Computer Show. Hawthorne Race Course, 3500 S. Cicero Ave. Air conditioned exhibit hall for dealers. Outdoor fleamarket spaces free. 8AM - 2PM. 6 AM setup. Admission $5. Kids under 12 free. Talk in 145.25 MHz. Info: Ed Weinstein, WD9AYR, 7511 Walnut Ave., Woodridge, IL 60517. tel: 708-985-9256.

August 25 (Sun), Woodstock, IL - Tri-County Radio Group. McHenry County Fairgrounds, Rt. 47. Admission $5 at gate, free parking. Kids under 12 free. Info (voice/fax) (708)658-1678.

August 25 (Sun) - Vermilion County ARA, Danville, IL. Info: Gary Denison, KA9SKS, 14704 East 2750 North Rd., Danville, IL 61834-5610. tel: 217-759-7389.

August 28 - 30 - Antique Radio Club of Illinois, Elgin, IL. RadioFest96. Holiday Inn Holidome and Convention Center, 345 River Road, Elgin, IL 60123 Ph. (708)695-5000, (847)695-5000 After 01/20/96. Info: Jeff Aulik, 1708 Parkview Ave., Rockford, IL 61107 or Carolyn Knipfel, RR 3, 200 Langhorn, Morton, IL 61550.

SEPTEMBER

September 8 (Sun) - Bolingbrook ARS, Joliet, IL. Info: Ed Weinstein, WD9AYR, 7511 Walnut Ave., Woodridge, IL 60517, tel: 708-759-7005

September 13-15 (Fri, Sat, Sun) - Peoria, IL. ARRL National Convention. Info: Ron Morgan, KB9NW, PO Box 3508, Peoria, IL 61612-3508, tel: 309-694-2649

I built one....and am VERY happy with the end result. There were a few minor problems, but the customer service at Ten-Tec is AMAZING. They sent me replacement parts for parts "I" screwed up. (FREE). If you need to talk to someone...you pay for the call, but you actually get to talk to someone who knows about the kit.

I can't wait to get my next kit.....I had a ball building this one!

In KISS mode, the connection is established and maintained by the
software you use, not the TNC firmware.

A is correct. The antenna you purchased was probably a NMO150, which can be tuned from ~140-180mhz. The coil should have come with a cutting chart to give an approximate length for a certain frequency. I've purchased several antennas from Larsen for buisness and amateur use and have been quite satisfied.

Here in Oregon the Larson Antennas come with a wip and length
instructions for the different frequencies which can be reached with a
given coil. I think you have to cut like 1 1/2 inches from the wip
for 146mhz. I have to get a new whip for mine cause the end broke
off.

The 416 is the same radio internally as the 415. I used the mod for
the 415 to modify my 416. Your will loose the auto repeater offset
function just the the 411.

gary@ke4zv.atl.ga.us (Gary Coffman) wrote:

> . . . it was Tom's taking a flamethrower to the article, author,
>and QST from message one on this thread which has led to all the
>heat and personal attacks that have followed.

Gary, I went back and read "message one" again. It may indeed
have been destined to draw attack, but any criticism of QST or
its contributors seems to evoke that response. At the very
least, Tom's post was no more inflammatory than many of your own.

>It would *appear* that Tom harbors an unexplained grudge
>against Svetlana and its products. Perhaps they wouldn't give
>him promotional samples, hmmm?

Making this claim against a professional engineer is inexcusable.
You should be ashamed to have said it.

< and from another of your posts >

>It was your wild, vicious, and totally unwarranted attack on the
>integrity of the QST editors . . .

Tom has by no means impuned the integrity of QST editors. In fact,
some of his responses were:

"They (as they still claim) refuse to accept articles
that may contain a conflict of interest. The refusal to
mix business and technical data is a key way to help insure
technical data is unbiased."

"Actually QST does not welcome such input, they flatly
refuse it!"

"But QST has always had high technical standards, it's a
shame to see the standards errode. QST was always above
allowing self promoting articles, it's a shame to see that
occuring more and more frequently."

Nowhere in any of this does Tom claim that publication of the
article might be the result of anything more than an oversight.
His posts have consistently focused on the technical errors and
conflict of interest that he saw in the article, rather than the
underlying reasons that might be responsible for it being printed.

Gary, I think you have a disagreement with Tom that's due to
differences of opinon that you consider legitimate. However,
these recent attacks deserve apology.

The FT-736 has a built-in power supply...you can add that to the price
of the 790 if you are comparing apples to apples.

>I didn't expect they would lost connection !
> Can anyone help ? Are there special instructions required ?

KISS does not support AX.25. It is simply a channel management and
modem management protocol. When you put the TNC in KISS mode, you
have to do the layer 2 protocol (AX.25 link layer, slip, ppp, etc)
via software running on the host computer.

In other words, it is the AX.25 layer that supported the connected
mode link. When you go into KISS, you are no longer doing AX.25 in
the TNC so the link is lost.

Has anyone built the Ten Tec 2M kit?
How does it compare to a rig from the big 3 in RF terms (Intermod, distortion, etc). I am not interested in out of band reception or DTMF paging. I am looking for a basic 2M radio that I can put together and maintain.

I hope it's better than the Ramsey kit.

>the SWR @ 146MHz down to 1.1:1 . So either A) the salesman didn't know
>what he was talking about B) Larsen tunes thier whips lousy, or C) the
>salesman handed me the wrong whip.

I have Larsen 2m and 2/70 antennas (both NMO and a 2/70 glass mount) and love
them. HOWEVER...

The salesman was mistaken; only their dual band antennas are "precut"; all their
single band antennas come with a chart that shows what length the antenna
"should" be cut to, though I'd trust an SWR meter as the final arbiter.

Now if you want strange, I have three Larsen 2/70 antennas, two of the
"cellular coil" type and one with the enclosed coil. The enclosed coil was the
only antenna that was fine out of the box. Both of the "cell" type dual band
antennas were precut too short! However, Larsen sent me longer versions of
both that I cut to size free of charge. Great folks at Larsen. (BTW, they
both ended up about 1/4" to 1/2" longer than the pre-cut antennas...)

Hello All

I am interested in getting a dsp box to enhance my ic-706. I am looking
for experience or recommendations on which box to get. I have read most of the
articles. The w9gr box looks good for cost and features, plus it is fun
building the kit. TimeWave? MFJ? JPS?

PS. I might be interested in a used dsp box if it can be purchased for
less than the w9gr box (provided it has the most recent software, firmware).

In article <4m966p$eju@nfs1.pe.net> connect@pe.net (Keith Motte) writes:
>I'm thinking of purchasing a new HF mobile rig and wanted to know which is the
>best mobile rig to buy. Is it the Alinco DX-70, ICOM 706, Kenwood TS-50 or
>Yeasu FT900. Rig will be used in auto as well as a base unit. Also it would be
>helpful if I had reviews on each radio.

Well, it's not the Kenwood, so that cuts your list to 3.

If the smallest size, full power on 6m, 2m capability, wide VHF receive,
and a remarkable set of control and interface options are important to you,
then you have only one choice, the IC-706.

If low price, only 10 watts on 6m, and no 2m, but wrapped in a pretty
small package, are acceptable to you, then the Alinco joins the fray.

If a stronger HF receiver and an autotuner are important, but it doesn't
matter to you that there is no 6m or 2m capability, and you can tolerate
the larger size in the car, then the Yaesu becomes the choice.

None of these radios have killer defects, and none of them are
perfect. They emphasize different things. I was swayed by the
mix of features on the IC-706, and I'm satisfied with my choice.
You might want to go a different way. The Alinco offers good
value, and the Yaesu offers the best HF performance, but the
differences are really more a matter of degree than a good/bad
choice. For instance, I like the clean Icom control system, some
people like the cluttered Yaesu approach better. The Alinco
display and controls seem too small to me, others think that
they are fine, etc. Go play with the radios in person for an
hour or two and make up your own mind which strikes your fancy.
Unless what you really need is a FT-1000MP, one of these radios
will likely make you happy.

>the tetrodes and pentodes produce more odd order harmonics.

Well Claude, that's why tetrodes and pentodes were developed, to
improve the linearity of the transfer curve over that of the triode,
to offer greater power gain in the linear part of the curve, and in
most cases to avoid the need for neutralization too. But the behavior
when any of them reach clipping is the same. And clipping still produces
only odd order harmonics.

There are two factors here that we shouldn't confuse. One is the
performance of the amplifier in clipping, and the other is performance
of the amplifier before it reaches clipping, IE ordinary distortion
due to a nonlinear transfer characteristic. The latter is always
undesirable, while the former is inevitable when an amplifier is
heavily overdriven, and can only be ameloriated by good circuit design,
IE the higher order odd harmonics can be attenuated by suitable output
filtering. The output transformer can serve that purpose for most
tube amplifiers.

From: frediam@mcs.com
Message-ID: <4mc5bo$9jg@Nntp1.mcs.net>
Source record: 201798

I am thinking of buying a Yaesu FT-900AT for mobile use. Anyone have any comments on using this radio in the car? How about the FT-900CAT? This a new version with a Collins mechanical filter installed. CAT costs $150-$200 more. Any thoughts on whether or not the mechanical filter is worth the added price?

I'm also trying to identify a relatively low profile mobile HF antenna to put on a company car which already has a vhf/uhf dual band antenna on it. Any thoughts?

Thanks in advance for any comments.

Hi Tom here... I have for sale 2 Regency 16ch programable mobiles.
They have 30W output, keyboard programable, mobile mtg brackets,
power cords, mics & all paperwork... They have programming switch
added to back of radio for on the fly re-programming.

They have been set-up for Emergency service rigs 140Mhz - 180Mhz.
broad banded, running 25W at the moment, an working in the 2 mtr
band. Type Accepted... So should be usable in other services as well.
They have scan, priority, skip, monitor & Tx & Rx pls <programable>
built in. It can have 2 different PL's <1 tx & 1 rx>...

Still with their original boxes, never pressed into service...
Tested to check functions on 2 mtrs... <We can guarenty they work.>
Area has gone 800Mhz trunked... <Reason for selling>

Will sell one or both, $235.00 each shipped.... Both for $450.00...

Contact me via e-mail or thru packet KD4QHH@K4DPZ.#Gnsvl.Fl.USA.NA.

Tnx De Tom 73

(RMS)
>or 23.26 volts peak. Added to the -56 volts static bias, that gives
>79.26 volts between grid and cathode. So the 77.22 volts peak drive
>is still within the correct range.

No, if the resistor is bypassed it raises the cathode to some value between the voltage calculated by the RMS and peak currents, not to the value of the peak current as calculated by that resistance.

Such circuitry also causes phase delays in the cathode bias voltage and can and usually does produce non-linearity. The effect is that the bias "looks correct" during a single tone test, or an incomplete paper analysis, but in reality it may be (and usually is) a good bit off, adding distortion.

If the cathode resistor of an AB1 amplifier is properly unbypassed, the cathode adds correct phase negative feedback, and subtracts from the grid drive voltage at a rate of between 1.414 and 2.818 times the metered plate current (plus the screen current). This system lowers efficiency but greatly improves IMD performance. This effect is inherent in grounded grid amplifiers but doesn't necessairily hurt efficiency in them.

>Obviously, the 68 db product for a *single* tone, is the third
>*harmonic* level of the amplifier when driven CW fashion. Product
>in this case may be a poor choice of words. It is a product of the
>amplifier, but it isn't a product in the conventional mixing sense.

Product is the wrong word, the correct word is HARMONIC. And harmonic has nothing directly to do with the type of tube used. I believe that was the incorrect point you made, that the 68 dB had something to do with the fact it was a tetrode?

>This isn't IMD. The IMD number is for the two tone test, of course.
>The first two products in that case are spaced at 2 kHz and 4 kHz
>from the (suppressed) carrier frequency, and are -38 db and -48 db
>respectively.

Again the details are somewhat lacking, dB what? Below a single tone or
the peak output?

-38 db isn't spectacular, an 8877 or 3CX800 will do much better than that
in a fixed power level two tone test. I've measured 8877's at over -43 dB
below PEP for third order and -52 dB in a fixed two tone test. A two tone
fixed power level test isn't accurate for evaluating SSB, in particular
with tetrodes.

All of that aside, where is the big "tetrode distortion advantage" you
touted while being so openly critical of my technical analysis and
ability? It certainly doesn't appear in those numbers!

>>Perhaps you have harmonics confused with second order products and IMD?
>
>From context, it should be obvious what I meant, but I do admit I
>didn't phrase it well. Look at the plots yourself at oak.oakland.edu.

You phrased it wrong, just like when it was implied the FCC IMD
requirements were more stringent at VHF than at HF.

>>You (incorrectly) made the following statements:
>>
>>1.) Tetrodes are cleaner than than triodes.
>
>They generally are. Let me select the best tetrode amplifier for
>a given power gain and you choose the best triode amplifier for
>the same power gain, and I'll wager the tetrode will be cleaner.

Untrue, tetrodes specially designed for SSB, like the 4CX600, are very
clean when the scrren is regulated to the nth degree, and the amplifier is
professionally tiuuned with a spectrum analyzer. But we were talking about
4CX800's and 4CX1600's in amateur applications. Compare them to any
similar grounded grid triode like the 3CX800 or 4CX1600 and they will lose
handily. ESPECIALLY when tuned by an amateur and especially when the grid
circuit and screen circuits are cheaply oversimplified.

> That should even be obvious if you compare the triode and tetrode
equations.

Anyone understanding the entire scope of design problem would certainly
believe as I do. With a ten to fifteen dB gain amplifier integrated into a
typical amateur radio system, there isn't any truth in the perception that
a tetrode produces a cleaner signal. As a matter of fact, the exact
opposite is true. The broad general statement that all tetrodes are more
cleaner than triodes is also untrue. Compare the 3CX5000 to a 4CX5000, the
4CX1600 to 3CX1500, and 3CX800 to the 4CX800, especially in working
circuits adjusted without the aid of a spectrum analyer.

And especially with marginal design to integrate them in a complete system.

>>2.) VHF operators are more skilled than HF operators.
>
>I believe that to be true, for VHF operators using high power
>vacuum tube amplifiers. That's mostly EME and MS types, who
>generally have built the amplifier themselves (there being
>very few commercial amplifiers to purchase). I would claim
>that they are likely to be more knowledgeable about the operation
>of their amplifiers than someone who burned the plastic for
>an Ameritron and twisted the knobs for maximum smoke (the more
>typical case among HF operators as you stated yourself).

Do you have any supporting data showing VHF operators to be more skilled than HF operators? Is that why they have no code tickets and restricted privileges at VHF, because operator skill automatically increases with frequency? What has Ameritron to do with any of this? Please tell me more.

>>3.) VHF amateur amplifiers have tighter IMD restrictions than HF amps.
>
>Indeed, spelled out in 97.307 (d) and (e). Spurious products must
>be down 40 db for HF amps and 60 db for VHF amps. Don't blame me,
>the FCC makes the rules.

Spurious emissions are not defined as close in IMD. If they were, there wouldn't be a single solid state VHF amp on the market today! Spurious emissions are out of band emissions, like harmonics or parasitics.

I file about five to ten FCC TA's a year for amateur products, and I can assure you IMD measurements are not required. The only requirement related to IMD is 97.307 (a) and (b).

The FCC refers IMD as "emissions resulting from modulation", since they are a normal and inevitable part of modulation processes. Spurious emissions are all products not directly related to modulation of the signal.

>And you ignored the cathode resistor.

And you ignored the effects of bypassing, and describing how it was done.

You seem angry about something I said. Tell me specifically what it was and I'll appologize. I certainly didn't me to provoke you to such a state of open hostility. Can you give me an example of a wild, vicious, and unwarranted remark so I understand exactly what you mean?

Another thought came to mind.

Besides obvious control grid to cathode linearity problems created from phase shift or delay at syllablic rates when the cathode is "floated" by a series resistance (in parallel with some capacitance), a more severe problem creeps in. The tube is moved closer to cut-off if the cathode is not allowed to return to ground at during the neagtive grid portion of each cycle exactly in step with the RF signal!

For example, consider a class AB amplifier at the edge of cutoff. Adding a few volts of positive cathode voltage not only reduces the effective current by increasing the bias voltage, it also reduces the effective screen voltage. Moving the screen to cathode voltage around carelessly at an audio rate is absolutely the last thing that should be done in a SSB amplifier.
